INDEX

COL—H 0 6733 - 214 - RP 844

Abalone (*Haliotis midae*) : Isolation of 2-Aminoethylphosphonic Acid from Phospholipids of the (A. J. de Koning), 113
Abbott, Dr. D. C. : Stationary Phase in Paper and Thin-Layer Chromatography, *review*, 982
Abdullah, Mukhtar, and French, Prof. D. Reversible Action of Pullulanase, 200
Abeles, F. B. : Ethylene Production from Linolenic Acid, 23–5
Abeles, Thomas P., and Ashworth, M. J. : Neutron Activation Analysis and Archaeology, 9–11
Aberdeenshire Gabbros : Olivine-Liquid Reaction and the Depth of Crystallization of the East (Dr. M. J. O'Hara and Prof. F. H. Stewart), 830
Aberdeenshire : Weathered Biotite from Strathdon, (Dr. M. J. Wilson), 1188
Abies balsamae (Linnaeus) Miller : Balsam Fir (E. V. Bakuzis and H. L. Hansen), *review* by Dr. C. J. Taylor, 343
Abortion in Guinea-pigs : Prenatal Loss of Foetuses and (M. J. Edwards), 223
Abrams, Gerald D., Mull, John D., and Bishop, J. E. : Normal Flora and Acute Inflammation, 1072
(+)—Abscisin II ('Dormin') in Plant Extracts by Spectropolarimetry. Identification and Estimation of (Prof. J. W. Cornforth et *al.*), 627
Abscisin : Stimulation of Flowering in Certain Short-day Plants by (Dr. H. M. M. El-Antably and Prof. P. F. Wareing), 328
Absolute Disintegration Rate of Technetium-99*m* : Measurement of the (I. W. Goodier and A. Williams), 614
Absorption in Aqueous Solutions of Certain Inorganic Sulphates : Ultrasonic (Dr. F. Fittipaldi), 835
Absorption Changes in Blue-green Algae at the Temperature of Liquid Nitrogen (Dr. B. C. Mayne and D. Rubinstein), 734
Absorption and Dispersion of Liquid Water : Submillimetre (Dr. J. E. Chamberlain et *al.*), 790
Absorption in Irregular and Regular Urchins and their Probable Relation to Outflow of Spherule-coelomocytes : 'Skin Digestion' and Epidermal (E. Pequignat), 397–9
Absorption by the Mouse and Rat Urinary Bladder of Glycine, Tryptophan and Glucose (Prof. G. T. Bryan and C. R. Morris), 857
Absorption Spectra of Cadmium and Zinc Atoms trapped in Noble Gas Matrices (W. W. Duley), 624
Absorption Spectra of Excited Atoms and Excited Ions produced by Isothermal Flash Photolysis of Metal Carbonyls in the Gas Phase (Dr. A. B. Callear and R. J. Oldman), 730
Absorption-spectrum of Haemoglobin of Leeches (Dr. A. E. Needham), 427
Absorption of Thyroid-stimulating Globulin from Thyrotoxic Sera by Organ Homogenates (Dr. D. J. El Kabir, N. Benhamou-Glynn, D. Doniach and Dr. I. M. Roitt), 319–21
Abstracts for Geography, 990
Abundance Analysis of the Peculiar Star *HD* 101065 (Dr. A. Przybylski), 20–2
Acacias in South Africa : Exotic (T. H. Hawkins), 577
Academy of Sciences : U.S., 784
Leopoldina German, Elections, 785
Acceleration at the Rutherford, 1099
2-Acetamidofluorene and 3-Methylcholanthrene : Differences in Binding to Rat Liver Deoxyribonucleic Acid *in vivo* (M. B. Sporn and C. W. Dingman), 531
Acetate in Biosynthesis by Sulphate-reducing Bacteria : Role of Carbon Dioxide and (Yu. I. Sorokin), 551
Acetate and Other Carboxylic Acids as Precursors of Ethylene (M. S. Gibson and R. E. Young), 529
Acetoin and Oxygen : Stimulation of Fermentation in Yeasts by (W. A. Scheffers), 533
Acetonaemic Dairy Cow : Blood Adenine Nucleotide Levels in the Normal and the (Dr. G. D. Baird), 863
Acetyl-l-carnityl CoA in the Brains of Narcotized Rats. Acetylcholine-like Activity of (Prof. E. A. Hosein and Albert Orzeck), 731
3-Acetyl-5-(4-fluorobenzylidene)4-hydroxy-2-oxo-2 5-dihydrothiophen. A New Type of Cytotoxic Immunosuppressive Agent : (Dr. T. J. Franklin *et al.*), 638
N-Acetyl-D-galactosamine into Blood Group Substance. Microsomal Incorporation of (H. Tuppy and W. L. Staudenbauer), 316
Acetylcholine from the Cerebral Cortex during Stimulation of the Optic Pathway : Release of (Dr. B. Collier and Dr. J. F. Mitchell), 424
Acetylcholine and Choline Acetylase in Squid Giant Axon, Ganglia and Retina (Dr. P. Rosenberg, Dr W.-D. Dettbarn and Dr. M. Brzin), 858
Acetylcholine-like Activity of Acetyl-l-carnityl CoA in the Brains of Narcotized Rats (Prof. E. A. Hosein and A. Orzeck), 731
Acetylcholine. Efflux of Prostaglandin from Adrenal Glands Stimulated with (P. W. Ramwell et *al.*), 273
Acetylcholine. Properties and Structures of Lecithin Monolayers containing Potassium Ions or (A. Hyono and S. Kuriyama), 300
Acetylcholine in Rat Slow Muscle : Sensitivity to (Dr. R. Miledi and Dr. J. Zelená), 855
Acetylcholine and other Substrates of Cholinergic Systems : Structure of (Dr. F. G. Canepa, Dr. P. Pauling and Dr. H. Sorum), 907–9
Acetylcholinesterase Activity in Denervated Muscles of Young Rats : Formation of New Sites of (Prof. L. Lubinska and Dr. J. Zelená), 39–41
Acetylcholinesterase Molecules at Motor Endplates of the Mouse : Number and Location of (Dr. A. W. Rogers, Dr. Z. Darzynkiewicz, Prof. E. A. Barnard and Dr. M. M. Salpeter), 1003–6
Acid Dyes in Methanol. Preferential Staining of Collagen by (T. N. Salthouse), 1277
Acid Mucopolysaccharides by Fibroblasts and Serosal Cells : Formation of (Dr. D. Lovell, A. E. Clark and Prof. R. C. Curran), 1173
Acid Phosphatase Preparation. Pyridoxal and Pyridoxamine Phosphate Breakdown by an (M. J. Andrews and Dr. J. M. Turner), 1159
Acidification of Soil : Stimulation of Nitrification following Temporary (Dr. M. L. Blasco and Dr. A. H. Cornfield), 1187
Acids : Formation of Esters from Acids by Brewer's Yeast. Formation from Unsaturated (Dr. K. Nordstrom), 99
Acipenser. Lift produced by the Heterocercal Tail of (Dr. R. McN. Alexander), 1049
Acoustic Factor in Letter Cancellation (Dr. D. W. J. Corcoran), 658
Acoustic-gravity Waves during Thunderstorm Formation. Mechanism for the Generation of (A. D. Pierce and S. C. Coroniti), 1209
Acoustical Society : British, 144
Acromegalic Subjects (Dr. B. J. Boucher), 1288
Actidione. Induction of Tyrosine Transaminase in Rat Liver by (Prof. S. Fiala and E. Fiala), 530
Actinomycin *D* and 7, 12-Dimethylbenz (*a*) anthracene : Inhibition of RNA Synthesis in Mouse Skin by (Dr. V. G. Flamm et *al.*), 541–3
Actinomycin *D* and the Regulation of Apoferritin Synthesis in Rat Liver (Y. Yoshino, J. Manis and Prof. D. Schachter), 538
Activation Analysis in Protein Tracer Studies : Stable Bromine and (Prof. P. Fireman et *al.*), 547
Activation, Deactivation and Destruction Steps in Chemical Kinetics : Interrelations of (Dr. M. Robson Wright and Dr. P. G. Wright), 1110–3
Actomyosin of Human Vascular Smooth Muscle (Dr. M. L. Mallin), 951
Adam, Dr. G. D. Physical Principles of Magnetism, *review*, 451
Adams, A., *et al.* Personality and Personal Illness, *review* by Sir Aubrey Lewis, 338
Adams, Prof. C. W. M. : Biology of Neuroglia : Progress in Brain Research, Vol. 15, *review*, 452
Adams, Dr. C. W. M., and Morgan, R. S. : Autoradiographic Demonstration of Cholesterol Filtration and Accumulation in Atheromatous Rabbit Aorta, 175
Adams, Prof. J. A. S., et *al.* : Possible Rubidium-Iron Covariance in Potassium Feldspars, 829
Adamson, Dr. Richard H., and Burger, Prof. J. W. Bromination of Fluoresceins by the Dogfish, *Squalus acanthias*, 755
Adaptation. Animal Conflict and (Prof. J. L. Cloudsley-Thompson), *review* by Dr. L. Harrison Matthews, 54
Adaptation to Displacement : Intermodal Transfer of (B. Craske), 765
Adaptations, Reflex Activity and the Brain : Compensatory (E. A. Asratian), *review* by Dr. H. Jackson, 453.
Adapting : Man (Prof. R. Dubos), *review* by Prof. N. W. Pirie, 978
Addiction in Britain Now : Drug (Prof. D. R. Laurence), 1203
Adelaide : University of, Appointment, 991
Adelie Penguins and a Crabeater Seal from Antarctica : DDT Residues in (Prof. W. J. L. Sladen et *al.*), 670–3
Adenine during the Hydrazine Degradation of Deoxyribonucleic Acid : Loss of (B. W. Ellery and Dr. R. H. Symons), 1159
Adenine Nucleotide Levels in the Normal and the Acetonaemic Dairy Cow : Blood (Dr. G. D. Baird), 863
Adenosine Diphosphate : Aggregation of Guinea-pig Platelets by (Dr. J. W. Constantine), 162–4
Adenosine Diphosphate and Blood Platelets : Magnesium, (A. Hughes and Dr. R. S. Tonks), 106
Adenosine Diphosphate : Possible Mechanism of Aggregation of Blood Platelets by (Dr. E. W. Salzman et *al.*), 167–9
Adenosine 3′, 5′-monophosphate on Rat Striated Muscle : Insulin-like Effects of (Dr. P. M. Edelman et *al.*), 1017–9
ATPase in Epithelia noted for Active Transport. Significance of the Histochemical Demonstration of (Dr. J. McD. Tormey), 820–2
Adenosine Triphosphatase in Wheat Roots : Effect of Calcium and Strontium on the Preferential Formation of an (R. E. Johnson and W. A. Jackson), 869
ATP : Creatine Phosphotransferase Activity in Guinea-pigs with Experimental Muscular Dystrophy : Serum (Prof. J. W. C. Bird and F. Carabello), 95
Adenosine Triphosphate. Inhibition of the Aggregation of Dissociated Embryo-chick Fibroblast Cells by (V. A. Knight et *al.*), 1008–10
Adenosylethionine on 5-Methyl-tetrahydrofolate-homocysteine Transmethylase : Effect of (J. F. Morningstar, jun., Prof. R. L. Kisliuk and Dr. J. A. Stekol), 732
Adenovirus 12 Virion-free 'T' Antigen from Infected Cells inhibited with Cytosine Arabinoside (Dr. A. C. Hollinshead and Dr. R. J. Huebner), 1381–3
Adipose : pH Decline in the Two Layers of the Panniculus (Prof. J. D. Sink), 861
Admissions to Universities, 25
Adrenal Glands Stimulated with Acetylcholine : Efflux of Prostaglandin from (P. W. Ramwell et *al.*), 273
Adrenalectomized Animals : Response to Vitamin D in (Dr. E. Czarnowska-Misztal et *al.*), 96
Adrenalectomized Rats after X-irradiation : Liberation of 5-Hydroxytryptamine in the Brain Stem of (Dr. D. Palaic and Prof. Z. Supek), 970
Adrenalin on Epidermal Mitotic Activity. Accelerating and Decelerating Actions of (Prof. W. S. Bullough and E. B. Laurence), 715
Adrenaline and Adrenergic Blocking Agents on the Basal Oxygen Consumption of the Perfused Rat Heart : Effect of (Dr. A. Hauge and Dr. I. Øye), 998 (Dr. D. R. Challoner), 999
Adrenergic-Receptors and Non-Shivering Thermogenesis (Prof. E. Schönbaum, Prof. G. E. Johnson, Prof. E. A. Sellers and M. J. Gill), 426
Adrenergic Blocking Agents on the Basal Oxygen Consumption of the Perfused Rat Heart : Effect of Adrenaline and (Dr. A. Hauge *et al.*), 998–1000
Adrenergic Transmission of the Carotid Chemoreceptor Impulses in the Toad : Evidence for (Dr. K. Ishii, Dr. Kasuko Ishii and Dr. K. Honda), 1057
Adsorbed Hydrocarbons : Exchange Reactions in the Radiolysis of (P. J. Dyne and N. H. Sagert), 1153
Adsorption of Oxygen on Ultra-thin Titanium Films (F. P. Fehlner), 1035
Adsorption from Solutions of Non-Electrolytes (J. J. Kipling), *review* by Dr. D. A. Haydon, 664
Advisers : Scientific, No More Mandarins, 1086
Aedes aegypti : Pertinacity of Host-seeking Behaviour of (Dr. W. J. Strauss et *al.*), 759

Aedes aegypti (L.) by Pupal Treatment : Chemosterilization of (G. B. White), 1372
Aerodynamic Shapes Theory of Optimum (edited by Prof. A. Miele), *review* by Dr. G. J. Hancock, 53
Aeronautics and Astronautics, Vol. 7, Heat Transfer in Structures : Monographs in (H Schuh), *review* by R. Hoyle, 74
Aerosol from Heated 80 · 20 Nickel-Chromium Wire : Chromium Trioxide (P. Goldsmith *et al*), 475–7
Afebrile Rabbits : Demonstration of Endogenous Pyrogen in (Dr. J. N. Sheagren and S. M. Wolff), 539
Aflatoxin in Malaysia, 357
Africa Bats of West (D. R Rosevear), *review* by Dr. D. L. Harrison, 65
Africa : Exotic Acacias in South (T H. Hawkins), 577
Africa · Pig Trypanosomiasis in, 1207
African Lion : Urea Cycle Enzyme Activities of Liver of the (Dr. G. W. Brown, junr.), 1367
Aftershocks, see Alaskan Earthquake, 893–6
Agar, Dr. W T., and McLaughlin, Dr R. J W : Removal of Magnesium from Underground Waters using Lime, 1210
Agar-plaque Formation . A Comparative Study of the Cluster and (Dr O. B. Zaalberg *et al.*), 544
Age for the Barwell Meteorite : Potassium-Argon (N H. Gale *et al.*), 620
Age on the Composition of Bovine Nasal Cartilage : Effect of (Mrs. A. Tin-Wai Goh and Dr D. A. Lowther), 1270
Age Determination . A Method of preparing Sperm Whale Teeth for (Mrs J. M. Bow and C. Purday), 437
Age Determinations on Granites, Pegmatites and Veins from the Kibaran Belt of Central and Northern Katanga (Congo) (L. Cahen, J. Delhal and G. Monteyne-Poulaert), 1347–9
Age and Haemoglobin-splitting Activity in Chicken Muscle : Relationship between (M. D Berman and A. W. Kotula), 1271
Age and following Intravenous Papain : Comparison of Changes in the Chemical Composition of Rabbit Cartilage Matrix with (Prof. T. T. Tsaltas and Dr. K. A. Greenawald), 1237–9
Age and Nephrectomy on E-Lysine Acylase of Rat Kidney : Effect of (Prof. Woon Ki Paik and Sangduk Kim), 735
Age and Polarity of the Turkana Lavas, North-west Kenya (T A. Reilly, Dr. A E. Mussett, P. K S. Raja, R L. Grasty and J Walsh), 1145
Ages Younger than 1,000–1,500 Years using Natural Silicon-32 'Dating' Ground Waters of (V. N Nijampurkar *et al.*), 478–80
Agglutination Assays for Detection of Leucocyte Antigens in Man · A Comparison of Lymphocytotoxic and (J. Bodmer *et al*), 28–31
Aggregating Agents · Modification of the Electrokinetic Response of Blood Platelets to (Dr J R. Hampton and Dr J. R. A Mitchell), 1000–2
Aggregation of Blood Platelets by Adenosine Diphosphate : Possible Mechanism of (Dr. E W Salzman, D. A Chambers and L. L. Neri), 167–9
Aggregation of Dissociated Embryo-chick Fibroblast Cells by Adenosine Triphosphate : Inhibition of the (V. A. Knight, Prof B. M. Jones and Dr P. C. T. Jones), 1008–10
Aggregation of Dissociated Embryonic Chick Cells at 3°C (Dr. W. D Ball), 1075
Aggregation of Guinea-pig Platelets by Adenosine Diphosphate (Dr. J. W Constantine), 162–4
Aggregation of Human Platelets by Dextrans (D. P. Dhall, D R. Harper, Dr. F. N. McKenzie and N. A. Matheson), 745
Aggregation of Rabbit and Guinea-pig Platelets by Oxime Esters (Dr. J. W. Constantine and Dr. F A. Hochstein), 164–7
Aggregation between Sponges and the Anthozoan *Anemonia sulcata* : Mixed Cell (Prof. M. Sarà *et al.*), 1168
Aggregation in Sponges Bispecific Cell (Prof. M Sarà *et al*), 1167
Agnosia : Speech Disorders : Aphasia, Apraxia and (Lord Brain), second Edition, *review* by Dr. M. Kinsbourne, 980
Agricultural Revolution in South Lincolnshire (Dr. D. Grigg), *review* by G. E Fussell, 561
Agriculture, Fisheries and Food : Ministry of : Animal Health : 1865–1965, *review* by Prof A Robertson, 1304
Agriculture : Plantation (Dr. P. P. Courtenay), *review* by Dr. W. R. Stanton, 62
Agustin, Conrado E., and Chow, Dr. B. F. : Premature Birth in Rats induced by Ethionine Injection, 1271
Ahmad, Prof F. : An Estimate of the Rate of Continental Drift in the Permian Period, 81–3
Ahrens, Prof L. H. · Chapter on Comparative Geochemistry in Applied Geochronology (E. I. Hamilton), *review* by Prof. D. York, 49
Ahrens, Prof. L. H., *et al.* : Observations on Caesium Enrichment and the Potassium/Rubidium/Caesium Relationship in Eclogites from the Roberts Victor Mine, South Africa, 1025–7
Aid : International (I. M. D. Little and Mrs J M Clifford), *review* by Sir William Slater), 662
Aimpoint in the Presence of Zero Ballistic Dispersion · Effectiveness of Patterns or Groups of Weapons released with a Single (Dr. E. R. Terry and E. V Gadecki), 686
Ainsworth, Prof. E. J , and Mitchell, F. A, : Decreased Radiation Mortality in Dogs treated with Typhoid-Paratyphoid Vaccine, 321–3
Ainsworth, Prof. E. J , Phillips, T. L., and Kendall, K. : Influence of Aminoethylisothiouronium Bromide-hydrobromide and Hypoxia on Recovery from Radiation Injury in Mice, 323
Ainsworth, Dr. G C. : The Genus *Aspergillus*, *review*, 342
Pilzkrankheiten bei Insekten, *review*, 666
Ainsworth, Dr. G. C., and Sussman, A. S. (edited by) · The Fungi, Vol. I · The Fungal Cell, *review* by Dr. J R. S. Fincham, 61
Air Concentrations of Lead-210 at Winchester, Massachusetts : Local Ground-level (B. Shleien and Dr A. G Friend), 579
Air : Glacier Depth-sounding from the (Dr. S Evans and Dr. G de Q. Robin), 883–5
Air Movement and Termite Behaviour (Dr. P. E. Howse), 967
Air, Separation of, by Low Temperature Methods · Design Atlas : Plant and Machinery for the (edited by I P. Usyukin), *review* by Dr N. Booth, 1198
Air in a Uniform Field : Electric Strength of Compressed (A. G. James *et al*), 403
Aircraft using a Single Counter . Radiation Measurements in Commercial (Prof. V. D. Hopper and W R. Rawlinson), 473–5
Airlines : Politics and the (Prof. D. Corbett), *review* by R. Brightman, 230
Airy Shaw, H K. : Bestimmungstabellen der Gallen (Zoo- und Phytocecidien) an Pflanzen Mittel- und Nordeuropas, Band I, *review*, 772
Ajmar, Dr. Franco, *et al.* Electrophoretic Demonstration of Stromal Effects on Haemolysate Glucose -6-phosphate Dehydrogenase and 6-phosphogluconic Dehydrogenase, 813–5
Aksoy, Prof. Muzaffer, *et al.* : Distribution of Haptoglobin Types in Turkish People, 315
Alaska : Diploid *Gymnocarpium dryopteris* (L.) Newman in (V. Sorsa), 1375
Alaskan Earthquake of March 28, 1964, and Major Aftershocks by Low Ocean Tide Loads · Triggering of the (E. Berg), 893–6
Albareda, Prof. José Maria : *Obituary*, 1313
Albin, Maurice S., White, R. J., Locke, G. E., and Kretchmer, H. E. : Spinal Cord Hypothermia by Localized Perfusion Cooling, 1059
Albright, Prof Joseph F., *et al* : Significance of a Single-hit Event in the Initiation of Antibody Response, 1383
Albumin in Healthy and Athero-sclerotic Individuals : Effect of Alimentary Lipaemia on the Glycoproteins and the Congo Red-binding Capacity of (S. Csögör and J. Mody), 545–7
Alcaligenes faecalis : Separation of Two Kinds of Polymerase from (Dr. K. Hori *et al.*), 604–8
Alcohol in Body Fluids : 'Endogenous' (G. W. Walker and Dr A. S. Curry), 1368
Alcohol Dehydrogenases in Endocrine Tissue : Histochemical Distribution of (M M Ferguson *et al.*), 1277–9
Alcohol Dehydrogenases : Proposed Catalytic Role for Histidine in Pyridine Nucleotide-linked (Dr. H. J. Ringold), 535
Alcoholics and Cases of Peptic Ulcer : Transaminase Deficiency in (Dr. L. Rutter), 538
Aldehydes to Collagen and Elastin Matrices : Binding of Aliphatic (Dr R. A. Milch *et al.*), 1042
Aldehydic Groups in Collagen and Other Tissue Components : Free (Prof. R. P. Davis and R Jarvis), 318
Alder, Dr. J F : Strength, Fracture and Fatigue of Materials, *review*, 51
Alderson, Dr. Thomas and Clark, Prof. A. M. : Interlocus Specificity for Chemical Mutagens in *Aspergillus nidulans*, 593–5
Aldosterone on the Lachrymal Gland Action of (E. Bott, J. R. Blair-West, J. P. Coghlan, D A Denton and Prof. R. D. Wright), 102
Alexander, G. V., and Rowland, R. H. : Estimation of Zinc-65 Background Levels for Marine Coastal Waters, 155–7
Alexander, Prof K. J. W . The Best Use of Economic Resources, *review*, 70
Alexander, Dr Peter : *Obituary* of Prof. Ferdinand Herčík, 12
Alexander, Dr. R McN : Lift produced by the Heterocercal Tail of *Acipenser*, 1049
Alfisi, M., *et al* : Effects of Light on 3, 4-Benzpyrene Carcinogenesis, 824
Algae at the Temperature of Liquid Nitrogen Absorption Changes in Blue-green (Dr. B. C. Mayne and D Rubinstein), 734
Alimentary Lipaemia, Effect of, on the Glycoproteins and the Congo Red-binding Capacity of Albumin in Healthy and Atherosclerotic Individuals (S. Csögor and J Mody), 545–7
Alimentary Tract of the Rat to the Hyperphagia of Chronic Alloxandiabetes : Anatomic Adaptation of the (Dr. E L. Jervis and Dr. R J. Levin), 391–3
Aliphatic Aldehydes to Collagen and Elastin Matrices : Binding of (Dr R A. Milch *et al.*), 1042
Alkali Feldspars : Order in (Dr J B Jones), 1352
Alkali Measurements from the Vema Seamount of the South Atlantic Ocean : Isotopic and (J. A. Cooper and Dr J R Richards), 1245
Alkaline Province, New Zealand : Olivine Nodules in a Phonolite of the East Otago (J. B. Wright), 519
Alkaloids as Possible Intermediaries in Plant Metabolism (Prof. J. W Fairbairn and A. Paterson), 1163
Allard, S. (edited by) · Selected Constants · Optical Rotatory Power, I*a* Steroids, *review* by Prof W. Klyne, 1197
Allen, Prof C W. Solar Radio Astronomy, *review*, 559
Allen, Dr N. P. : Appointment as Deputy Director (A) of the National Physical Laboratory, 248
Allene at 77°K : Reaction of Hydrogen Atoms with *Cyclo*propane and with (Dr A N Hughes and Dr. J. H. Purnell), 255–7
Allergology Dictionary : Lexicon Allergologicum, *review* by Dr. D C. Dumonde, 563

Alper, Miss Tikvah, and Hornsey, Miss S. : Unexpected Dose-rate Effect in the Killing of Mice by Radiation, 212
Alpha-carotene : Metabolism of (Prof. J S. McAnally and Dr. C. D. Szymanski), 1366
α-Chymotrypsin · Structural Specificity of (G. L. Neil *et al.*), 903–7
Alpha-radioactivity of Human Blood (V. Hasson and Dr. R. D. Cherry), 591–3
Al-Shamma, Ali, *et al.* · A New Class of Hypotensive Agents, 742
Alternation and Exploration in Rats : Spontaneous (A. W. Still), 657
Alternation in the Rat : Memory and Spontaneous (A. W. Still), 400
Aluminium · Oxyfluorides and Basic Fluorides of (Dr. R. L. Johnson and Dr. B. Siegel), 1256
Alvsaker, J. O., *et al.* : Presence in Lipoproteins from Human Serum of a Crystalline Blue Fluorescent Substance of Unknown Structure isolated from Bovine Liver, 917–9
America : Latin (Dr. J P. Cole), *review* by Sir Dudley Stamp, 771
America, 1945–47 : A Peril and a Hope : Scientists' Movement in (A. K. Smith), *review* by R. Brightman, 451
American Soils : 'Polyspheroids' from (Dr. S W. Orenski *et al.*), 221
Americium in Human Blood Serum Proteins · *In vitro* Distribution of (Dr. G. Boocock and Dr. D. S. Popplewell), 1283
Amerine, Maynard A., Pangborn, R. M., and Roessler, E B. : Principles of Sensory Evaluation of Food, *review* by Dr. D. C. Berry, 665
Ames, Ira H., and Mitra, J. : Spontaneous Reduction of Somatic Chromosomes in *Haplopappus gracilis*, 973
Amide Bond by Gas-Liquid Chromatography : Investigation of Steric Effects about the (Dr B. Halpern *et al*), 837
Amin, B S , *et al.* . 'Dating' Ground Waters of Ages Younger than 1,000–1,500 Years using Natural Silicon-32, 478–80

Amino-acid 'Code' and of Selection for Conformation in the Evolution of Proteins : Role of the (Dr. C J. Epstein), 25–8
Amino-acid Components in Fossil Calcified Tissues (Dr. W. G. Armstrong and Dr. L B. Halstead Tarlo), 481
Amino-acid Composition of the Acquired Pellicle of Human Tooth Enamel (Dr. W G. Armstrong), 197
Amino-acid Composition of the Egg Capsule of the Whelk *Buccinum undatum* L : Carbohydrate and (S. Hunt), 436
Amino-acid : Occurrence of 5-Hydroxy-L-tryptophan as a Free Plant (Dr. E. A Bell and L. E Fellows), 529
Amino-acid Protection of Ultra-violet-irradiated *Bacillus subtilis* (Dr. D. E. Hunt), 761
Amino-acid Substitutions in Haemoglobins and the Mutation Process (Prof. F. Vogel and G Rohrborn), 116
Amino-acids · Stereochemical Basis for the Division between Protein and Non-protein (Dr. P. Dunnill), 1267
γ-Aminobutyrate . *In vivo* Conversion of γ-Hydroxybutyrate into (Prof. G. Della Pietra *et al.*), 733
Aminoethylisothiouronium Bromidehydrobromide and Hypoxia on Recovery from Radiation Injury in Mice · Influence of (Prof E J Ainsworth, T. L. Phillips and K Kendall), 323
2-Aminoethylphosphonic Acid from Phospholipids of the Abalone (*Haliotis midae*) Isolation of (A J. de Koning), 113
Amino-laevulinic Acid Synthetase in Normal and Porphyric Human Livers : Activity of (Prof K. Nakao, Dr. O. Wada, Dr. T Kitamura, Dr. K. Uono and Dr. G Urata), 838
Ammah-Attoh, V. . Laboratory Rearing of the Parasitic Stages of *Boophilus decoloratus* (Koch, 1844) on the European Rabbit (*Oryctolagus cuniculus*), 43–4, 77
Ammonia from Nitrogen and Water : Radiation-induced Synthesis of (N. Getoff), 940
Amnesic Syndrome · Deranged Memory · Psychonomic Study of the (Dr. G A. Talland), *review* by Prof. O. L. Zangwill, 126
Amphetamine and Catecholamines on Startle Response and General Motor Activity of Albino Rats : Effect of (Charles E. Cladel, jun., Prof. M. H Cho and R. D McDonald), 864
Amylase Inhibitor in Human Serum · Search for a Naturally Occurring (S Hayashi, Dr. R. L. Searcy, Prof. J. E. Berk and E. M. Hardy), 92–4
Amylase in Pancreatectomized-Enterectomized Dogs : Hypoglycaemia, Elevated Liver Glycogen and Diminished Liver (N. Hiatt), 423
Amyloidosis and Tolerance Experimental (Prof E. Letterer and Dr. R Kretschmer), 390
Anaemia : An Unstable Protein causing Inclusion-body (R W. Carrell *et al.*), 915
Anaesthesia in Animal Surgery : Simple Catheter for Intermittent Intravenous (J F. Hulka *et al*), 1389
Analysis and Fractionation of Polymers (edited by J Mitchell, jun., and F W. Billmeyer, jun.), Symposia, 1964, *review* by Prof. C. E. H Bawn, 57
Analysis of the Peculiar Star *HD* 101065 : Abundance (Dr. A. Przybylski), 20–2
Analysis in Protein Tracer Studies · Stable Bromine and Activation (Prof. P. Fireman *et al.*), 547
Ananthakrishnan, Dr. R : Meteor Luminosity and Meteor Ionization, 402
Anantharaman, T R., Luo, H. L , and Klement, jun., W. Formation of New Intermetallic Phases in Binary Eutectic Systems by Drastic Undercooling of the Melt, 1040
Anatomic Adaptation of the Alimentary Tract of the Rat to the Hyperphagia of Chronic Alloxan-diabetes (Dr E. Lesly Jervis and Dr. R. J Levin), 391–3
Anatomy of Plants . Royal Society Lectures (N. Grew) reprinted from 1682 Edition, *review* by Prof. C. W. Wardlaw, 343
Andjelković Dr. D., and Milošević, Prof. M. P. : Reactivation of Paraoxon-inactivated Cholinesterase in the Rat Cerebral Cortex by Pralidoxime Chloride, 206
Andrews, M. Jean and Turner, Dr. J. M. : Pyridoxal and Pyridoxamine Phosphate Breakdown by an Acid Phosphatase Preparation, 1159
Anemonia sulcata : Mixed Cell Aggregation between Sponges and the Anthozoan (Prof. M. Sarà *et al*), 1168
Angel, B. R , *et al* : Distribution of Substitutional Nitrogen Donors in Synthetic Diamonds, 692–4
Angerer, L., and Jones, E : Electroluminescence in Transformer Oil and Liquid Paraffin in High D.C Fields, 1219
Angles on Temperature : Dependence of Contact (H. Schonhorn), 896
Aniline Mustard · Cure of Mice bearing Advanced Plasma Cell Tumours with (Dr. T. A Connors and Dr. M E. Whisson), 866
Animal Behaviour : Readings in (edited by Prof T. E. McGill), *review* by Dr. A. D. Blest, 456
Animal Conflict and Adaptation (Prof. J. L. Cloudsley-Thompson), *review* by Dr. L. Harrison Matthews, 64
Animal Health · 1865–1965—Century of Endeavour to Control Diseases of Animals (Ministry of Agriculture, Fisheries and Food), *review* by Prof. A. Robertson, 1304
Animal Hormones and by Puromycin : Induction of Enzyme Activity in Pea Tissues by (Dr. M A Venis), 534
Anions in Nylon : Factors affecting the Mobilities of (J. Marshall and Dr. J. A. Medley), 729
Anisopus Larvae (Diptera) in Cases of Intestinal and Urino-genital Myiasis (K. G. V. Smith and E. Taylor), 852
Anomalous Excitation of OH Microwave Emissions from H-II Regions : Suggested Mechanism for the (Dr. A. H Cook), 611
Anovulatory Bilateral Hermaphroditic Rat (Dr. D C Johnson), 1287
Antarctic Ice Cap Telluric Current Experiment on the (Prof V. P Hessler and J. Jacobs), 190
Antarctic Ice Sheet : Variation in Solar Insolation to the South Polar Region as a Trigger which induces Instability in the (Prof. A. T. Wilson), 477
Antarctic Lake · Problems of Heat Transfer in Lake Vanda, a Density Stratified (R. A. Hoare), 787–9
Antarctica (edited by T. Hatherton), *review* by Dr. T. R. Kaiser, 72
Antarctica : DDT Residues in Adelie Penguins and a Crabeater Seal from (Prof. W. J. L. Sladen *et al.*), 670–3
Antarctica : Emperor Penguin Colony at Beaufort Island, Ross Sea (Dr. B. Stonehouse), 925
Antares from Lunar Occultations : Brightness Distribution of (J H. Taylor, jun.), 1105–8
Antenna Main Lobe : Brightness Temperature of Solar Active Regions determined from Drift Curves of the Sun across a Broad (Dr. H. W. Urbarz), 891–3
Antenna : New NASA Tracking, 574
Anthozoan *Anemonia sulcata* : Mixed Cell Aggregation between Sponges and the (Prof. M. Sarà *et al.*), 1168
Anthropology · The Past in the Present (Dr J. M. Coles), 251
Antibilharzial Nitrothiazole Compound by *Schistosoma mansoni* : Selective Uptake of an (Dr R. Hess *et al.*), 964
Antibiotics : Consequences of Inhibition of *Escherichia coli* by Tetracycline (I. A Holmes and Dr. D. G. Wild), 1047
Protection of Phagocytized Bacteria from the Killing Action of (B Holmes *et al.*), 1131
Antibodies : Location of Spore and Vegetative Antigens of *Bacillus cereus* by means of Ferritin-labelled (R. O. Thomson *et al*), 760
Antibodies responsible for Haemagglutination, Cytotoxicity and Enhancement : Transplantation Immunity . Localization in Mouse Serum of (Dr. G. A. Voisin *et al.*), 138
Antibodies to *Plasmodium falciparum* by Gel-diffusion Techniques : Demonstration of Circulating (I. A McGregor, P. J. Hall, K. Williams, C. L S. Hardy and Dr M W. Turner, 1384–6
Antibodies of Restricted Specificity : Structural Heterogeneity of L Chains in (M. Lanckman), 1379
Antibodies in Young Rabbits : Appearance of Natural (W. A Hook, A. J. Toussaint, L A. Simonton and Prof. L. H Muschel), 543
Antibody Antigenicity of Soluble Protein in the Presence of High Levels of (W. J Herbert), 747
Possible Genetic Basis for Specific Pattern in (Sir Macfarlane Burnet), 1308–10
Antibody following Antigen-Antibocy Combination : Effect of Antigen on the Structural Configuration of Homologous (Dr. C. S Henney and Dr. D. R. Stanworth), 1071
Antibody against "Australia Antigen" in Rabbits : Production of (Dr L. Melartin and Prof. B. S. Blumberg), 1340
Antibody Formation : Molecular and Cellular Basis of (edited by J. Šterzl), Symposium 1964, *review* by Prof S. Cohen, 560
Antibody Inhibition by a Minimal Dose of Antigen and Response to a Sudden Increase of the Dose (J. Gras and M. Dalmau), 430
Antibody *in vitro* by Lymph Node Fragments using Absorbable Gelatin Sponges : Synthesis of (Prof. M Richter, A. Juhasz, B Drechsler and J Myers), 645
Antibody Nature of the Inhibitor to Antihaemophilic Globulin (Factor VIII) (Dr. E Bidwell, K. W. E. Denson, G. W. R. Dike, Dr. R. Augustin and G. M. Lloyd), 746
Antibody required to promote Phagocytosis of One Bacterium : Number of Molecules of (Prof. D. Rowley and K. J. Turner), 496–8
Antibody Production by Single Spleen Cells a Comparative Study of the Cluster and Agar-plaque Formation (Dr. O. B. Zaalberg, V. A van der Meul and J M. van Twisk), 544
Antibody Response · Significance of a Single-hit Event in the Initiation of (Dr. R. A. Brown *et al.*), 1383
Antigen Adjuvants : Antigenicity of Soluble Protein in the Presence of High Levels of Antibody : a Possible Mode of Action of the (W. J. Herbert), 747
Antigen-Antibody Reaction : Reaction Kinetic Studies of the (Prof R P. Tengerdy and W. H Small), 708–10
Antigen from Infected Cells inhibited with Cytosine Arabinoside Adenovirus 12 Virion-free 'T' (Dr. A. C. Hollinshead and Dr. R. J. Huebner), 1381–3
I Antigen in Leukaemic Patients (Dr. T Feizi and Dr. R. M. Hardisty), 1066
Antigen by Mouse Eosinophils : Rapid Uptake of Tritiated (Prof A. N. Roberts), 266–9
Antigen in Organ and Tissue Cultures of Hyperplastic Human Thyroid Gland : Persistence of an Organ-specific (A G. Nicol and Dr. J. S. Beck), 1227–9
Antigen and Response to a Sudden Increase of the Dose : Antibody Inhibition by a Minimal Dose of (J. Gras and M. Dalmau), 430
Antigen on the Structural Configuration of Homologous Antibody following Antigen-Antibody Combination : Effect of (Dr. C. S. Henney and Dr. D R. Stanworth), 1071
Antigenic Properties of Soluble Elastins and their Use in Detecting Soluble Elastin in Ligament Extracts (Prof. D S. Jackson, Dr. L. B. Sandberg and Dr. E G. Cleary), 195
Antigenicity of Conjugates of Arsanilic Acid in Inbred Guinea-pigs (Dr. S. Ben-Efraim and Dr S Leskowitz), 1068
Antigenicity of Soluble Protein in the Presence of High Levels of Antibody : a Possible Mode of Action of the Antigen Adjuvants (W. J Herbert), 747
Antigens of *Bacillus cereus* by means of Ferritin-labelled Antibodies : Location of Spore and Vegetative (R. O. Thomson *et al.*), 760
Antigens of Human Erythrocytes : Quantitative Relationship of the Rh-like (LW) and D (M. B Gibbs), 642
Antigens in Man : Leucocyte (J Bodmer *et al.*), 28–31
Antigens · Species Distribution of Gastrointestinal (Prof. R C Nairn and Dr. W G R. M de Boer), 960–2
Antihaemophilic Globulin (Factor VIII) : Antibody Nature of the Inhibitor to (Dr. E. Bidwell *et al.*), 746
Antiquity : Inorganic Raw Materials of (Dr. A Rosenfeld), *review* by H. W M. Hodges, 231
Antirabic Immunity : Mucolipids of the Brain in the Process of Formation of Post-vaccinal (Dr. L. P. Gorshunova *et al*), 1279
Antisera against Dye-Protein Complexes : Cytotoxic Effects of (F Seelich *et al.*), 645
Anti-transferrin-dependent Haemagglutination in Adult *C*$_3$*H* Mice during Injections of Casein and in Untreated Suckling *C*$_3$*H* and *DBA*/2 Mice (Dr. P. Ebbesen), 1125–7
Anti-viral Drug (M and B 7714) and Bilirubin Conjugation (Dr. T Hargreaves), 639
Anwar, Dr. H O : Application of the Principle of Extremum to a Submerged Discharge, 287
Anwar, Prof R A., and Oda, G. : Structure of Desmosine and Isodesmosine, 1254
Aorta : Autoradiographic Demonstration of Cholesterol Filtration and Accumulation in Atheromatous Rabbit (Dr. C. W. M Adams and R. S. Morgan), 175
Apatite : Substitutions for Phosphate Ions in (N. A. Trueman), 937
Aphasia, Apraxia and Agnosia : Speech Disorders (Lord Brain), Second Edition, *review* by Dr. M. Kinsbourne, 980
Aphids : Haemolymph Pigments of (Dr J. H. Bowie *et al.*), 395–7
Apical Cell Number in Gemmae of *Marchantia polymorpha* L. : Relation between Extrapolation Number and (M. W. Miller), 748
Aplysia : Habituation at the Synaptic Level in (Dr. J. Bruner and Dr. L. Tauc), 37–9
Apoferritin Synthesis in Rat Liver : Actinomycin *D* and the Regulation of (Y. Yoshino *et al.*), 538
Apparao, K. V S R , and Narasimham, N. A. : Isotope Shifts in the Near Infra-red Bands of Diatomic Sulphur, 1034
Appearance of Man (Pierre Teilhard de Chardin), *review* by M. C. Burkitt, 71
Appenzeller, Otto : Reflex Vascular Function in Unanaesthetized Rabbits, 1058
Apples : α-Farnesene in the Natural Coating of (Dr. F E. Huelin and Dr. K. E. Murray), 1260
Apples (*Pyrus malus*) : Effects of Gamma Radiation on Freeze-dehydrated (Prof. C Y. Lee and Prof D. K. Salunkhe), 971
Appointments, 14, 145, 250, 358, 679, 785, 991, 1101, 1208, 1317
Apraxia and Agnosia : Speech Disorders : Aphasia, Second Edition (Lord Brain), *review* by Dr. M. Kinsbourne, 980
Aqueous Solutions of Certain Inorganic Sulphates : Ultrasonic Absorption in (Dr. F. Fittipaldi), 835
Arachnida (Arthropoda) : Peritrophic Membranes in (O Van der Borght), 751
Arboviruses : Phenotypic Mixing between Group *A* (B. W. Burge and E. R. Pfefferkorn), 1397–9

Archaeocytes : RNA-storage Inclusions of Freshwater Sponge (Dr. J. R. Simons and Miss L. Muller), 847
Archaeological Identification : Inorganic Raw Materials of Antiquity, (Dr. A. Rosenfeld), *review* by H. W. M Hodges, 231
Archaeology : Functional (Dr. J M Coles), 146
Neutron Activation Analysis and (M J. Ashworth and T. P. Abeles), 9–11
Archambeau, John O., et *al.* Mammalian Radiation Lethality : A Disturbance in Cellular Kinetics, *review* by Miss T. Alper, 60
Arctic : Natural Levels of Lead-210, Polonium-210 and Radium-226 in Humans and Biota of the (Dr. R. B. Holtzman), 1094–7
Argon from Biotite in a Thermal Metamorphism Loss of (M. R Westcott), 83
Arihood, Sharon, and Light, R J. : Inhibition of 6-Methylsalicylic Acid Synthesis in *Penicillium patulum*, 629

Cavernicolous Crayfish : Functional Caudal Photoreceptor in Blind (Prof. J. L. Larimer), 204
Cell Aggregation between Sponges and the Anthozoan *Anemonia sulcata* : Mixed (Prof M Sarà, L Liaci and N. Melone), 1168
Cell Aggregation in Sponges : Bispecific (Prof. M. Sarà et al), 1167
Cell Cleavage in Polar Body Formation (Dr. G. G. Selman), 750
Cell Cycle of the Mouse Hair Follicle : Use of Multiple Biopsies for the Study of the (Prof M L. Griem), 213
Cell Injury in Myocardial Ischaemia Intracellular Plasma Protein : a Manifestation of (Prof S P. Kent), 1279–81
Cell Multiplication Rates during Development of the Primitive Cardiac Tube in the Chick Embryo (Dr. N. J. Sissman), 504–7
Cell Transformation by X-irradiation : *In vitro* (C. Borek and Prof. L Sachs), 276–8
Cell Wall Surface of the Higher Plants (Prof. F M. Scott), 1015–7
Cells at 3°C : Aggregation of Dissociated Embryonic Chick (Dr. W D Ball), 1075
Cells during Centrifuging . Compression of Human Red (E Ponder), 527
Cells in the Chinese Hamster . DNA Replication of Somatic (Dr O. H. Pflueger and Dr J J Yunis), 1074
Cells other than Lymphocytes : Effects of Phytohaemagglutinin *in vitro* on (Dr. H L. Joachim), 919–21
Cells mediated by Mycoplasmas Transformations in Hamster (Dr. I Macpherson and Dr. W Russell), 1343–5
Cells : Recent Advances in the Micro-irradiation of (Dr. P. P. Dendy), 17
Cells . Synthesis of Nucleic Acids and Nuclear Protein in Replicating Animal (Dr. J Seed), 993–5
Cells and Tissues in Culture (edited by Dr E. N. Willmer), Vol I and Vol. 2, *review* by Dr. J. A. Sharp, 125
Cellular Basis of Antibody Formation : Molecular and (edited by J. Šterzl), Symposium 1964, *review* by Prof. S. Cohen, 560
Cellular Control Systems and Radiosensitivity (J. S. Orr, C. S. Hope, J. Laurie and Dr. J. M. Stark), 699
Cellular Kinetics : Mammalian Radiation Lethality : A Disturbance in (Dr. V. P. Bond et al.), *review* by Miss T. Alper, 60
Cellular Location of the Genes controlling Penicillinase Production and Resistance to Streptomycin and Tetracycline in a Strain of *Staphylococcus aureus* (S. M Poston), 802–4
Cellular Transmission of Lymphosarcoma in Dogs (Dr. G. Moldovanu, Dr. A. E. Moore, Dr. M. Friedman and Dr. D. G. Miller), 1342
Cellulose *in vitro* and *in vivo* in Cotton Bolls : Comparison of the Biosynthesis of (Dr M. Marx-Figini), 754
Cellulose in Cotton Bolls by Different Light Intensities : Kinetics of the Biosynthesis of (Dr. M. Marx-Figini), 755
Cell-wall Lytic Enzymes on a Semidefined Medium by a *Streptomyces* : Production of Yeast (M. V. Elorza et al.), 442
Cenomanian of Southern Israel and Egypt : A New Oyster Species from the (G. Mishnaevsky), 517
Centenary of the Royal Microscopical Society : Charter (Dr. J. R. Baker), 564
Central Nervous System . Mast Cells in the (D J Campbell and J A. Kiernan), 756
Central Nervous System : Structural Specialization at Nodes of Ranvier in the (Dr. R. H. Laatsch and Dr. W. M. Cowan), 757
Centrifugation at 5g and 6g : Growth and Food Consumption of Labyrinthectomized Hamsters during Chronic (Prof. C C. Wunder et al.), 177–9
Centrifugation of the Eggs on the Sex of *Carausius morosus* Br. : Effect of (Dr. L. P. Pijnacker), 1184
Centrifuging : Compression of Human Red Cells during (E. Ponder), 527
Centron-Cortex and Cortex-Medullary Cord Junctions in the Rat Lymph Node, as seen in 1μ Paraffin Sections (Dr. D. W. Menzies), 431
Centrophenoxine on the Lipofuscin Pigments in the Neurones of Senile Guinea-pigs : Effect of (Prof. K. Nandy and Prof G. H. Bourne), 313
Cephalosporin C by Ultra-violet Light : Destruction of (Dr. A. L. Demain), 426
Ceramics : Science of (edited by G H. Stewart), Vol. 2, *review* by Dr. N. F. Astbury, 74
Ceramics 1964 : Special (edited by P. Popper), Symposium, *review* by J. H. Manning, 55
Cercal Stimulation recorded in the Cricket Brain : Response to (H. Dingle and S. S. Fox), 1050
Cercariae of *Echinoparyphium recurvatum* Linstow : Histochemical Studies on the Rediae and (Dr. A. J. Probert), 550
Cerebral Cortex : Distribution of Colloidal Particles in Extracellular Space and Synaptic Cleft Substance of Mammalian (Dr G. D. Pappas and Dr. D. P. Purpura), 1391
Synaptic Contacts on Axons in the (L. E. Westrum), 1289
Cerebral Cortex by Pralidoxime Chloride : Reactivation of Paraoxon-inactivated Cholinesterase in the Rat (Prof M. P. Milošević and Dr D. Andjelković), 206
Cerebral Cortex in Rat Foetus : Effects of Total-body X-irradiation in Single and Fractionated Doses on Developing (L. A. Jacobs and Prof. K. R. Brizzee), 31–3
Cerebral Cortex during Stimulation of the Optic Pathway : Release of Acetylcholine from the (Dr. B Collier and Dr. J. F. Mitchell), 424
Cereijido, Prof. Marcelino, et al. : Location of the Mechanism of Active Transport of Sodium across the Frog Skin, 597–9
Çetingil, Arif Ismet, et al. : Distribution of Haptoglobin Types in Turkish People, 315
Chadwick, Sir James (under the Scientific Direction of) : The Collected Papers of Lord Rutherford of Nelson, O M , F R.S., Vol. 3, *review* by Prof C. C. Butler, 73

ELDO : One White Elephant, 1085
Beginning and End, 1091
Wrong Repentance, 1194
Electric Field on the Capacity of Phospholipid Membranes : Influence of (A. V. Babakov, L N Ermishkin and E. A Liberman), 953–5
Electric Strength of Compressed Air in a Uniform Field (A. G. James, H McL Ryan and C. W Powell), 403
Electric Stress . Light Emission in *n*-Hexane under High (Dr. C W. Smith et al), 192
Electrical Biology Laboratory, 575
Electrical Conductivity and Photo-conductivity of Pure Benzene (E Pitts, G. C. Terry and F. W. Willets), 295
Electrical Simulation of Optics of Moving Media (Dr. A Bramley), 833
Electrical Stimulation of Rhinencephalic Structures in the Foetal Guinea-pig Respiratory Changes during (Prof R. M. Bergstrom et al.), 1176–8
Electrically Augmented Flame System Non-seeded (J C Gawen et al), 1149
Electricity Properties of Synthetic Good Conductors of (Prof. A. R Ubbelohde), 404
Electrocatalysts : Boron Carbide, a New Substrate for Fuel Cell (Dr. W. T. Grubb and Dr D W. McKee), 192
Electrode : Laser Interferometry of a Dropping Mercury (Prof. J. Leja and Prof. R. N. O'Brien), 1217–9
Electrodialysing with a Non-polarizing Membrane (Dr. M. Block), 626
Electrodynamics : Black-body Radiation Law deduced from Stochastic (M. Surdin et al), 405
Electrogenesis of the Sodium Pump in Frog Skeletal Muscle Denervation and the (R. P Kernan), 537
Electrokinetic Mechanism of Learning ? : A Possible (Dr R Eluf), 1127–31
Electrokinetic Response of Blood Platelets to Aggregating Agents : Modification of the (Dr. J. R Hampton and Dr. J. R A Mitchell), 1000–2
Electroluminescence of Transformer Oil and Liquid Paraffin in High D.C. Fields (E Jones and L Angerer), 1219
Electroluminescence in the Zinc Sulphide/Copper/Manganese System : D C. (A. Vecht and R. Ellis), 1251
Electrolytes : High-performance Hydrocarbon Fuel Cells with Fluoride (Dr. E. J Cairns), 161
Electromagnetic Interactions Lectures on Strong and (P. T Matthews et al.), *review* by Dr. J E Paton, 55
Electron Affinity and Protection in the Radiation Chemistry of Hydrocarbons : A correlation between (Dr. W V. Sherman), 1285
Electron Diffraction : Determination of Radial Distribution Functions by Elastic (Dr C. W. B Grigson and M F Tompsett), 86
Low-energy, 467
Electron Gas : Meissner Effect in a Classical (J. Pfleiderer), 614
l'Électron et la Lumière Matière et Photoluminescence Luminescence : (G. Monod-Herzen), *review* by Prof J C. Robb, 1199
Electron Microscope Observations of Pancreatic Islet Cells of the Early Chick Embryo (Dr Mitsuo Machino), 853
Electron Microscopic Identification of Autonomic Nerve Endings (K C. Richardson), 756
Electronmicroscopic Investigation Preparing Dispersions of Zinc Oxide Particles for (Dr W Peelaers), 88
Electron Microscopical Demonstration of Ferritin in the Dental Epithelial Cells of Urodeles (Miss M Randall), 1325
Electron Microscopy : Ferritin-labelled Enzyme : A Tool for (M A Benjaminson et al.), 1275
Penetrated Human Ovum studied by (Dr. L. Zamboni et al.), 1373–5
Electron Microscopy of Biological Material . Scanning (Dr. R F. W Pease and Dr. T L. Hayes), 1049
Electron Optics (Prof P. Grivet) : Revised Edition (A Septier), *review* by Dr V. E Cosslett, 232
Electron Paramagnetic Resonance Spectra of Bone and its Major Components (Prof R. O. Becker and A A. Marino), 583–8
Electron-scavenging Solute on the Radiolysis of *Cyclo*hexane : Effect of an (Dr R. Blackburn and Prof A Charlesby), 1036
Electron Spectroscopy and Chemical Binding (Dr A Fahlman, K. Hamrin, J Hedman, R. Nordberg, C Nordling and Prof K. Siegbahn), 4–8
Electron Spin Resonance Spectra associated with Nitrogen in Diamonds (H J. Bower and Prof M C R. Symons), 1037
Electron Spin Resonance Study of Thermal Effects in Irradiated Deoxyribonucleic Acid (J B. Cook and Dr. S. J Wyard), 526
Electron Spin Resonance in Surviving Rat Tissues (Dr. J R Mallard and M. Kent), 588–91
Electronic Counter : Size Analysis in the Sub-sieve Range by (O I Sopp and J. Moum), 724
Electronics Research and Development (Telecommunications) in the Ministry of Aviation : Director, 466
Electronics Star Catalogue, 357
Electrophoretic Demonstration of Stromal Effects on Haemolysate Glucose-6-phosphate Dehydrogenase and 6-Phosphogluconic Dehydrogenase (Dr. P E. Carson, Dr F Ajmar, F. Hashimoto and Dr. J E. Bowman), 813–5
Electrophoretic Patterns of Immune Globulin Chains and Fragments Use of Charged Thiol Reagents in Interpreting the (Dr A Feinstein), 135–7
Electrophoretic Separation of Two Plaque-type Variants of Encephalomyocarditis Virus (D. C Breeze and H. V. Thorne), 1080
Electrophoretic Ultra-violet Method Investigation of Ribonuclease Isozymes by an (Dr N. Ressler et al.), 695–8
Electrophoretic Variants of Human 6-Phosphogluconic Dehydrogenase : Genetics of Starch-gel (Dr J E Bowman et al), 811–3
Electroretinogram to recover after a Brief, High-intensity Light Stimulus : Inability of the (Prof S Buckser), 425
Electrostatic Generator at Oxford, 1099
El Kabir, Dr D. J., Benhamon-Glynn, N , Doniach, D., and Roitt, Dr. I. M : Absorption of Thyroid-stimulating Globulin from Thyrotoxic Sera by Organ Homogenates, 319–21
Ellenby, Dr. C , and Smith, L . Haemoglobin in a Marine Nematode, 1372
Ellery, B. W , and Symons, Dr. R H., Loss of Adenine during the Hydrazine Degradation of Deoxyribonucleic Acid, 1159
Ellis, R , and Vecht, A : Direct Current Electroluminescence in the Zinc Sulphide/Copper/Manganese System, 1251
ElNaghy, M A , and Shaw, Prof. M Correlation between Resistance to Stem Rust and the Concentration of a Glucoside in Wheat, 417
Elorza, Maria Victoria, Muñoz Ruiz, E , and Villanueva, J R : Production of Yeast Cell-wall Lytic Enzymes on a Semi-defined Medium by a *Streptomyces*, 442
Elsmore, B., et al . Positions of Radio Sources measured with the One-mile Radio Telescope, 22
Eluf, Dr. Rafael : Dependence of Synaptic Transmission on Protein Metabolism of Nerve Cells : a Possible Electrokinetic Mechanism of Learning ? 1127–31
Elution Volume versus Reciprocal Elution Volume in the Interpretation of Gel-filtration Experiments (Dr. G A. Gilbert), 299
Embryo : Electron Microscope Observations of Pancreatic Islet Cells of the Early Chick (Dr. M Machino), 853
Embryonic Cells of *Drosophila melanogaster* : Long-term Culture of (Dr. M. Horikawa et al), 183–5
Embryonic Chick Cells at 3°C : Aggregation of Dissociated (Dr. W. D Ball), 1075
Embryonic Development of the European Bug, *Pyrrhocoris apterus* 'Paper Factor' as an Inhibitor of the (Dr. K Sláma and Prof. C M Williams), 329
Emeleus, Prof K G. : Retirement from the Chair of Physics at the Queen's University, Belfast, 466
Emission of Gases in a High-voltage Discharge : Radio (Dr G. V. Mcgarl and Prof. J M. Marchello), 1214–7
Emission and Narrow Spectral Features : Observations of Circularly Polarized OH (Prof. A. H. Barrett and A. E. E. Rogers), 188–90
Emissions from H-II Regions Suggested Mechanism for the Anomalous Excitation of OH Microwave (Dr. A H Cook), 611
Emmons, R N., Inst. Lt -Cdr R G , et al : Distribution of Substitutional Nitrogen Donors in Synthetic Diamonds, 692–4
Emperor Penguin Colony at Beaufort Island, Ross Sea, Antarctica (Dr. B. Stonehouse), 925
Empirical Enzyme Rate Equations : Mechanistic Interpretation of (Dr A. J Davison), 1161
Enamel : Amino-acid Composition of the Acquired Pellicle of Human Tooth (Dr. W. G Armstrong), 197
A New Method for the Decalcification of Adult Human (B. Sundström), 1386
Encephalomyocarditis Virus : Electrophoretic Separation of Two Plaque-type Variants of (D C. Breeze and H. V. Thorne), 1080
Endocrine Regulation : Function of Neurosecretion in (Sir Francis Knowles and Prof. H. A. Bern), 271
Endocrine Tissue Histochemical Distribution of Alcohol Dehydrogenases in (M M. Ferguson et al.), 1277–9
Endogenous Pyrogen in Afebrile Rabbits : Demonstration of (Dr J. N. Sheagren and S M. Wolff), 539
Endoplasmic Reticulum Fragments isolated from Rat Liver Structural Aspects of Polyribosomes and (E. L. Benedetti et al), 1156
Endotoxic Bacterial Lipopolysaccharides revealed by Ion-exchange Column Chromatography Heterogeneity of (Prof. A Nowotny), 278–80
Endotoxin Mechanism of Action of Bacterial (Prof. J. Fine and Dr. R. Minton), 97
Endplates of the Mouse : Number and Location of AChase Molecules at Motor (Dr A. W Rogers et al), 1003–6
Energy Budget of *Populus sargentii* Leaves Transpiration Resistance and (D. F. Parkhurst and D M. Gates), 172–4
Energy . Ultrasonic (edited by E Kelly), *review* by Dr. C N Smyth, 1088
Engel, Prof. Stanford L , and Bodanszky, Dr. M. . Oxytocin and the Life-span of Male Rats, 751
Engineer in Society : Place of the (Lord Snow), 237
Engineering : Industrial Relations in (A Marsh), *review* by Air Commodore L. E. Jarman, 123
New Members of the National Academy of, 573
Science in Chemical (Prof P V. Danckwerts), 571–3
Sociology of, 886
Engineering Societies : International Conference of, 679
Engineers Year-Book for 1966 . Kempe's (edited by C E Prockter, under Direction of B W. Pendred), 71st Edition, Two Volumes, *review* by Prof T M. Charlton, 1307
Engines : Mechanochemical (Dr. I. Z. Steinberg et al.), 568–71
English Paracelsians (A G Debus), *review* by Dr. M. Boas Hall, 770
Enhancement : Localization in Mouse Serum of Antibodies responsible for Haemagglutination, Cytotoxicity and (Dr. G A. Voisin et al), 138
Enhancing Factor localized to the Muscle Cells in Man . Muscle Glycogen Synthesis after Exercise : An (J Bergstrom and E Hultman), 309
Enlotypy Allotypy and (Prof. B Cinader et al), 1291
Environmental Temperature on the Metabolic Response to Injury : Effect of (Miss R M Campbell and Sir David Cuthbertson), 206
Enzymatic Synthesis of Labelled Cytidine-5'-Diphosphate Ethanolamine (T. Chojnacki and R F. Metcalfe), 947
Enzymatic Transamination Molecular Mechanism for (Dr. M. Ya Karpeisky and Dr. V. I Ivanov), 493–6
Enzyme Activities of Liver of the African Lion : Urea Cycle (Dr. G. W. Brown, jun.), 1367
Enzyme Activity in the Fat Bodies of the Cockroach, *Leucophaea maderae* (F.) : Malic (N. Dubowsky and L Pierre), 1293
Enzyme Activity in Pea Tissues by Animal Hormones and by Puromycin Induction of (Dr. M. A. Venis), 534
Enzyme Activity in Washed Trypanosome Suspensions : Blood Platelets as a Source of (H Dixon), 428
Enzyme Caps on Lipid Droplets : 'Catalysomes', or (Sir Vincent Wigglesworth) 759
Enzyme : Ferritin-labelled (M. A Benjaminson et al.), 1275
Enzyme Rate Equations . Mechanistic Interpretation of Empirical (Dr A J. Davison), 1161
Enzyme : Regeneration of Yeast Protoplasts prepared by Snail (A. Svoboda and O. Nečas), 845
Enzyme System for Ethylene Production : Preparation and Properties of an (J. E Thompson and Prof M Spencer), 595–7
Enzymes to Cross-linked Dextran ('Sephadex') : Chemical Coupling of (Dr. R. Axén and Dr J. Porath), 367–9
Enzymes and DNA in Synchronous Cultures of *Schizosaccharomyces pombe* : Synthesis of (C J Bostock, Dr W. D. Donachie, Dr M. Masters and Prof. J M. Mitchison), 808–10
Enzymes in Rat Liver Influence of Cortisone on the Substrate-induction of (Dr. H. Kroger and B. Greuer), 200
Enzymes on a Semi-defined Medium by a *Streptomyces* : Production of Yeast Cell-wall Lytic (M. V. Elorza et al), 442
Enzymes : Separation of Two Different Substrates for Plasma Kinin-forming (Prof. S. Jacobsen), 98
Eosin Pulse Radiolysis of Aqueous (Prof. L. I. Grossweiner et al.), 1154–6
Eosinophils Rapid Uptake of Tritiated Antigen by Mouse (Prof A. N Roberts), 266–9
Ephemeris Time : Atomic Standards of Frequency and the Second of (W. Nicholson and D. H. Sadler), 187
Epidemic Processes : Stability of (W. Goffman), 786
Epidermal Absorption in Irregular and Regular Urchins and their Probable Relation to the Outflow of Spherule-coelomocytes : 'Skin Digestion' and (E. Pequignat), 397–9
Epidermal Mitotic Activity : Accelerating and Decelerating Actions of Adrenalin on (Prof. W. S. Bullough and E B Laurence), 715
Epithelia noted for Active Transport : Significance of the Histochemical Demonstration of ATPase in (Dr J. McD Tormey), 820–2
Epithelia : Role of Long Extracellular Channels in Fluid Transport across (Dr. J. M. Diamond and Dr. J. McD Tormey), 817–20

Epithelial Cells of Urodeles ; Electron Microscopical Demonstration of Ferritin in the Dental (Miss M. Randall), 1325
Epithelial Tissues : Method for extracting Mucoproteins from (I. Hakkinen et *al*), 1263
Epithelio-muscular Cells in *Hydra* : Migration of (Prof. S Shostak and M. Globus), 218
Epizootic of Equine Sarcoid (Dr. W. L. Ragland, G. H. Keown and Dr. J. R. Gorham), 1399
ε-Lysine Acylase of Rat Kidney : Effect of Age and Nephrectomy on (Prof. W. K. Paik and S Kim), 735
Epstein, Dr Charles, J. : Role of the Amino-acid 'Code' and of Selection for Conformation in the Evolution of Proteins, 25–8
Equations : Mechanistic Interpretation of Empirical Enzyme Rate (Dr. A. J. Davison), 1161
Equatorial Ionospheric Drifts (Prof. R. W. Morriss and Prof. A. J. Lyon), 617
Equatorial Latitudes with Satellite *Injun* 3 · Non-Eckersley-law Whistlers observed at (G. W. Pfeiffer et *al.*), 827
Equidae : Sex-linkage of the Glucose-6-phosphate Dehydrogenase Gene in (C. K. Mathai et *al.*), 115
Equine Granulosa Cells growing in Tissue Culture Progesterone Biosynthesis by (Dr. C. P. Channing), 1266
Equine Sarcoid : An Epizootic of (Dr. W. L Ragland et *al*), 1399
Erdem, Sakir, Aksoy, Prof. M., and Çetingil, A I. : Distribution of Haptoglobin Types in Turkish People, 315
Ermishkin, L. N , et *al* : Influence of Electric Field on the Capacity of Phospholipid Membranes, 953–5
Erythrocyte Phosphogluconate Dehydrogenase Polymorphism (C. W. Parr), 487–9
Erythrocytes : Inhibition of Haemagglutination by Benzylpenicillin adsorbed on (Prof. K. C. Watson), 1180
Peroxidation of Lipid from Normal and Paroxysmal Nocturnal Haemoglobinuria (W. D Meriwether and Dr. C. E. Mengel), 91
Quantitative Relationship of the Rh-like (LW) and D Antigens of Human (M. B. Gibbs), 642
Escherichia coli against Damage by Freezing : Inability of Decenylsuccinic Acid to protect (Prof. M Nakamura), 113
Escherichia coli β-Galactosidases: Effect of Thiols on (Prof. F. J. Reithel et *al.*), 1265
Escherichia coli B/r growing exponentially in Minimal Medium : Site of Lethal Damage by Ionizing Radiation in (Dr. R. J. Munson and Dr. B A. Bridges), 922–5
Escherichia coli and Rabbit Reticulocyte Ribosomes : Effect of Trypsin on (Dr R Zak et *al*), 169–72
Escherichia coli $B_{S-1}\gamma R$ · a Strain Resistant to X-rays and Sensitive to Ultra-violet Light (V. D. Zhestjanikov), 1231
Escherichia coli by Tetracycline Antibiotics · Consequences of Inhibition of (I A. · Holmes and Dr. D. G. Wild), 1047
Escherichia coli B after X-irradiations Breakdown of RNA in (I Pečevsky and · B. Miletić), 325
Esposito, Dr G , Faelli, A , and Capraro, Prof V. : Metabolism and Sodium Transport in the Isolated Rat Intestine, 307
Essays on Humanity, 144
Esters from Acids by Brewer's Yeast: Formation from Unsaturated Acids· Formation of (Dr. K. Nordstrom), 99
Esters : Aggregation of Rabbit and Guinea-pig Platelets by Oxime (Dr. J W. Constantine and Dr. F. A. Hochstein), 164–7
Estuaries · Rubbish in, 678
Etching of Metal and Semi-conductor Surfaces Laser-induced Thermal (R. J Murphy and G J Ritter), 191
Etching of Quartz · Ultrasonically induced (C. C. Connolly), 1251
Ethionine Control of NADP Synthesis in the Livers of Rats treated with (Dr. J B Clark and S. Pinder), 631
Ethionine Injection : Premature Birth in Rats induced by (Dr. B F Chow and C. E Agustin), 1271
Ethylamine · Tea as a Source of Urinary (A M. Asatoor), 1358–60
Ethylene : Acetate and Other Carboxylic Acids as Precursors of (M. S. Gibson and R. E. Young), 529
Ethylene Production from Linolenic Acid (F. B. Abeles), 23–5
Ethylene Production : Preparation and Properties of an Enzyme System for (J. E. Thompson and Prof. M. Spencer), 595–7
Ethyleneglycol Dinitrate (and Nitroglycerine) in Blood and Urine : Determination of Traces of (A F. Williams, W. J. Murray and B H. Gibb), 816
Ethylnitrosourea to Pregnant Rats Teratogenic and Carcinogenic Effects in the Offspring after Single Injection of (Prof. H Druckrey et *al*), 1378
Ettlinger, G , and Blakemore, C. B : Cross-model Transfer of Conditional Discrimination Training in Monkeys, 117
Eugenol Inhibition of β-D-Glucosiduronic Acid Conjugation by (Prof. K J. W. Hartiala et *al.*), 739
European Launcher Development Organization One White Elephant, 1085, Beginning and End, 1091, Wrong Repentance, 1194
Eutectic Systems by Drastic Under-cooling of the Melt Formation of New Intermetallic Phases in Binary (T. R. Anantharaman et *al.*), 1040
Eutectoid Temperature of the Iron-Oxygen System · Determination of the (Dr. N. Birks), 407
Evans, E. J , and Burnett, Prof. J. H. · Genetical Homogeneity and the Stability of the Mating-type Factors of 'Fairy Rings' of *Marasmius oreades*, 1368
Evans, Dr. S , and Robin, Dr G. de Q. : Glacier Depth-sounding from the Air, 883–5
Evolution . Internal Factors in (L. L. Whyte), *review* by Prof. W. H. Thorpe, 663
Evolution of the Nuclear Atom (G. K. T. Conn and H. D. Turner), *review* by Dr. W. M Currie, 1198
Evolution of Primate Societies (Dr. J. H Crook and J S. Gartlan), 1200–3
Evolution of Proteins": Role of the Amino-acid 'Code' and of Selection for Conformation in the (Dr. C J. Epstein), 25–8
Excitability : Laser Lesions : Changes in Retinal (A. N. Nicholson and M J. Allwood), 637
Excitation of OH Microwave Emissions from H-II Regions : Suggested Mechanism for the Anomalous (Dr. A. H. Cook), 611
Excitatory Neuromuscular Synapse : Chemical Transmission at the Insect (Dr. P. N R. Usherwood and P Machili), 634–6
Excretion of Xanthurenic Acid in the Urine of Women taking Progestogen-Oestrogen Preparations (Dr D P Rose), 196
Exercise : Muscle Glycogen Synthesis after (J. Bergstrom and E Hultman), 309
Exley, Dr C. S. : The Granitic Rocks of Haig Fras, 365–7
Exobiology : Current Aspects of (edited by G Mamikunian and M H. Briggs), *review* by Dr D. G. Rea, 663
Exosphere : Asymmetrical Stop Zones in Jupiter's (S. Gulkis and Dr. T. D. Carr), 1104
Exotic Acacias in South Africa (T H Hawkins), 577
Expedition to Mid-West Brazil : Royal Society/Royal Geographical Society, 784
Expenditure : Domestic Food Consumption and (Miss M. E. Cameron), 19
Exploration in Rats : Spontaneous Alternation and (A. W. Still), 657
Explosions Precursor Shock produced by 0 25-g Chemical (M. W. S. Mawbey and R. D. Rowe), 1035
Exposure to Polonium-210 · Depletion of Mouse Spermatogonia following (L. D. Samuels), 434
Exposure to Strange Males : Pregnancy Failure in Laboratory Mice after Multiple Short-term (Prof. R. K. Chipman et *al.*), 653
Extracellular Channels in Fluid Transport across Epithelia : Role of Long (Dr. J M. Diamond and Dr. J McD. Tormey), 817–20
Extracellular Recording of Converging Input on Cortical Neurones using a Flexible Micro-electrode (Prof. L. T. Rutledge and Dr. J. A. Duncan), 737–9
Extracellular Space and Synaptic Cleft Substance of Mammalian Cerebral Cortex : Distribution of Colloidal Particles in (Dr G. D. Pappas and Dr. D. P. Purpura), 1391
Extraction . Combined Ion Exchange-Solvent (Dr J. Korkisch), 626
Extrapolation Number and Apical Cell Number in Gemmae of *Marchantia polymorpha* L. : Relation between (M. W Miller), 748
Extremum to a Submerged Discharge : Application of the Principle of (Dr H O. Anwar), 287
Eye : Distribution of Selenium in the Tissues of the ([the late] H. H Taussky et *al*) 949
Plasticity of Reactions to Light in Frogs and a Possible Role for the Pineal (N. Mrosovsky and K. H. Tress), 1174
Eye Colour Mutations in *Dahlbominus* : Effects of Fast Neutrons on (W F. Baldwin and W G. Cross), 1396
Eysenck, Prof H. J. : Source Book in the History of Psychology, *review*, 69

Factors in Evolution · Internal (L L Whyte), *review* by Prof. W H. Thorpe, 663
Faelli, A , et *al* . Metabolism and Sodium Transport in the Isolated Rat Intestine, 307
Fahlman, Dr A , Hamrin, K , Hedman, J., Nordberg, R., Nordling, C., and Siegbahn, Prof. K : Electron Spectroscopy and Chemical Binding, 4–8
Faigle, Dr J W., et *al.* : Selective Uptake of an Antibilharzial Nitrothiazole Compound by *Schistosoma mansoni*, 964
Fair Isle and its Birds (K. Williamson and P Davis), *review* by Sir Landsborough Thomson, 236
Fairbairn, Prof. J. W., and Paterson, A : Alkaloids as Possible Intermediaries in Plant Metabolism, 1163
Fairley, Sir Neil Hamilton . *Obituary* by A W. Woodruff, 1205
'Fairy Rings' of *Marasmius oreades* . Genetical Homogeneity and the Stability of the Mating-type Factors of (Prof J. H Burnett and E J. Evans), 1368
Fall-out in Israel from the Second Chinese Nuclear Detonation . Fresh (A Eisenberg, A Donagi, Y. Prulov, E Shalmon and Y Feige), 833
Fall-out to the Southern Hemisphere : Transfer of Northern Hemisphere (R N. Woodward), 1244
Family Studies in the U S. and in Mexico · Population and (Dr. J. E. Bowman et *al.*), 811–3
Far Eastern Seas of the U S S R. : Polychaeta of the (Prof. P. V. Ushakov), *review* by Prof G. P. Wells, 456
Farish, O , and Tedford, Dr. D J : Photomultiplier Studies of the Temporal Growth of Ionization during the Formative Time of Spark Breakdown in Nitrogen, 721–3
α-Farnesene in the Natural Coating of Apples (Dr F. E. Huelin and Dr K E. Murray), 1260
Farr, Dr Richard S., and Kohler, Dr Peter F. . Elevation of Cord over Maternal IgG Immunoglobulin : Evidence for an Active Placental IgG Transport, 1070
Fascioliasis in Sheep and Cattle : New Drug for the Treatment of (A. W Broome and W G M Jones), 744
Fast Neutrons on Eye Colour Mutations in *Dahlbominus* : Effects of (W. F Baldwin and W G. Cross), 1396
Fat Bodies of the Cockroach, *Leucophaea maderae* (F) . Malic Enzyme Activity in the (N. Dubowsky and L L. Pierre), 1293
Fat Body of an Insect : Sequestration of Protein by the (Prof M. Locke and J V Collins), 552
Fatigue in Glasses : Dynamic (I Whitney et *al*), 730
Fatigue of Materials Strength, Fracture and (T Yokobori), *review* by Dr. J F Alder, 51
Fatty Acids during Histological Fixation : Reaction of Formaldehyde with Unsaturated (D Jones and Dr. G. A. Gresham), 1386–8
Fatty Acids formed by Platelets from Normal and Diabetic Subjects : Carbon-14 in Carboxyl Carbon of (Prof A. R. Hennes et *al.*), 839–41
Fecundity in *Plutella maculipennis* (Curt.) : Photoperiodism and (Dr. D. G. Harcourt and L. M. Cass), 217
Fecundity : Primordial Germ Cells and (M. W. Hardisty and J. Cosh), 1370
Feeding in Seals and Sea Lions : Visual Orientation and (E S. Hobson), 326

Light Intensities . Kinetics of the Biosynthesis of Cellulose in Cotton Bolls by Different (Dr. M Marx-Figini), 755

Light Measurements in Plant Growth Investigations (Prof O V S Heath · K J McCree), 752
Light-sensitive Systems Chemistry and Application of Nonsilver Halide Photographic Processes (Dr J Kosar), *review* by D J Fry, 982
Light Source for Immunofluorescence Microscopy . New High-efficiency (Prof M G Bals and V. G Velculescu), 1073
Light Stimulus · Inability of the Electroretinogram to recover after a Brief, High-intensity (Prof. S Buckser), 425
Light Transmission Filters for Visible (S Marti et *al*), 513
Lightning Hazards · Ionizing Radiation and (Prof J. E Roberts et *al*), 514
Lignin Biochemistry (Dr W J Schubert), *review* by Dr N J King, 57
Likelihood Function Distribution of the Derivative of the (Dr M L Tiku), 766
Lillegraven, A , and Hvinden, T. Caesium-137 and Strontium-90 in Norwegian Milk, 1960–1964, 580–3
Lime : Removal of Magnesium from Underground Waters using (Dr R J W. McLaughlin and Dr. W T Agar), 1210
Limestone New Mechanism for the Formation of Vertical Shafts in Carboniferous (A R Burke and P F Bird), 831
Limestones from Ice River, British Columbia Strontium Isotopes and Trace Elements in Carbonatites and (T Deans et *al*), 290
Lincolnshire Agricultural Revolution in South (Dr D. Grigg), *review* by G .E Fussell, 561
Lindop, Dr Patricia J , and Rotblat, Prof J . Induction of Lung Tumours by the Action of Radiation and Urethane, 1392
Line Spectra of Quasi-stellar Objects On the Interpretation of the (Prof G R. Burbidge, Prof M Burbidge, Prof F Hoyle and Dr C R. Lynds), 774–8
Linear and Non-linear Systems Dynamics of (P Naslin), *review* by Dr A. W. Gillies, 54
Ling, Miss Lee-Nien, et *al* Long-term Culture of Embryonic Cells of *Drosophila melanogaster*, 183–5
Linnett, Prof J W. · Valence Theory, *review*, 56
Linolenate . Malonaldehyde from the Autoxidation of Methyl (Dr T W. Kwon and Prof. H. S. Olcott), 214
Linolenic Acid Ethylene Production from (F B Abeles), 23–5
Linskens, Prof H F , and Krner, H : Interference Microscopy of the Pattern of Leaf Surfaces, 968
Lion Urea Cycle Enzyme Activities of Liver of the African (Dr G W. Brown, jun), 1367
Lions, Dr F , et *al* High-spin Five-coordinate Cobalt (II), 298
Lipaemia on the Glycoproteins and the Congo Red-binding Capacity of Albumin in Healthy and Atherosclerotic Individuals Effect of Alimentary (S Csogor and J Módy), 545–7
Lipaemia and Hepatic Steatosis in the Male Rat : Cortisone-induced (Dr R. B. Hill, jun , and F P. Rudè), 733
Lipase from *Torulopsis* · Purification and Properties of (H Motai, E Ichishima and F Yoshida), 308
Lipetz, Dr Ben-Ami Measurement of Efficiency of Scientific Research, *review* by R Brightman, 76
Lipid Droplets 'Catalysomes', or Enzyme Caps on (Sir Vincent Wigglesworth), 759
Lipid Metabolism in Rabbits Effect of Sporidesmin on (J A Peters), 601–3
Lipid Metabolism in *Tribolium* Genetic Control of (R F Costantino et *al.*), 221
Lipid from Normal and Paroxysmal Nocturnal Haemoglobinuria Erythrocytes : Peroxidation of (W D Meriwether and Dr. C. E Mengel), 91
Lipid-Water Systems : Structure of the Cubic Phase of (V Luzzati and F Reiss-Husson), 1351
Lipids on Blood · Effect of Dietary, 1206
Lipids of *Candida albicans* Effect of Inositol on the (Prof D E Bianchi), 114
Lipids induced by Carbon Tetrachloride Lipoperoxidation of Rat Liver Microsomal (Dr R O Recknagel and A K. Ghoshal), 1162
Lipids of Carious Human Dentine Histochemical Observations on the (H Allred), 748
Lipids of Photosynthetic Systems (A T James and B W Nichols), 372–5
Lipids as Related to Atherosclerosis : Metabolism of (compiled by F A Kummerow), Symposium 1963, *review* by Dr T B Begg, 341
Lipids of Sound Human Dentine : Histochemical Observations on the (H Allred), 646
Lipofuscin Pigments in the Neurones of Senile Guinea-pigs Effect of Centrophenoxine on the (Prof. K Nandy and Prof G H Bourne), 313
Lipoperoxidation of Rat Liver Microsomal Lipids induced by Carbon Tetrachloride (Dr R O Recknagel and A K. Ghoshal), 1162
Lipopolysaccharides revealed by Ion-exchange Column Chromatography . Heterogeneity of Endotoxic Bacterial (Prof. A. Nowotny), 278–80
Lipoproteins from Human Serum, Presence in, of a Crystalline Blue Fluorescent Substance of Unknown Structure isolated from Bovine Liver (P Laland, J O. Alvsaker, F Haugl, Prof J Dedichen, Prof S Laland and N. Thorsdalen), 917–9 (S Furberg), 919
Lipotropic Effect of Cold on Rat Liver (Dr. P Bobek and Dr E Ginter), 204
Lippmann, H , et *al* . Weltkarten zur Klimakunde, *review* by G. D. Robinson, 73
Liquid Fraction of Bee Venom . Collection of the (A. W Benton and Prof R. A. Morse), 652
Liquid Jet diffusing under Gravity · Flow Patterns in a Submerged (Dr S K. A Naib), 694
Liquid and Solid Cation Exchangers Hydration in (E Hogfeldt), 941
Liquid Water · Submillimetre Absorption and Dispersion of (Dr. J E Chamberlain et *al*), 790
Liquids on Polyethylene Dependence of Contact Angles on Temperature Polar (H Schonhorn), 896
Liquids with Temperature Variation of the Isothermal Compressibilities of (J C. McGowan), 1255
Little, I M D , and Clifford, Mrs J M · International Aid, *review* by Sir William Slater, 662
Littlewood, J E , on his 80th Birthday Papers presented to (edited by J D. Weston), Proceedings of the London Mathematical Society, Third Series, Vol 14A, *review* by Prof. T A A Broadbent, 666
Littlewood, Dr K., et *al* : Some Observations on Ions of Low Mass Number in Hydrocarbon Flames, 946
Litwin, Stephen D , and Kunkel, Dr H G γ-Globulin Genetic Factor related to Gm(a) but localized to a Different Portion of the same Heavy Chains, 866
Liver : Actinomycin D and the Regulation of Apoferritin Synthesis in Rat (Y. Yoshino et *al*), 538
Influence of Cortisone on the Substrate-induction of Enzymes in Rat (Dr H Kroger and B Greuer), 200
Lipotropic Effect of Cold on Rat (Dr P Bobek and Dr E. Ginter), 204
In vitro Metabolism of *p,p'*DDT in Pigeon (Dr P J Bunyan et *al*), 1048
Presence in Lipoproteins from Human Serum of a Crystalline Blue Fluorescent Substance of Unknown Structure isolated from Bovine (P Laland et *al*), 917–9
Structural Aspects of Polyribosomes and Endoplasmic Reticulum Fragments isolated from Rat (E L Benedetti et *al*), 1156
Liver by Actidione Induction of Tyrosine Transaminase in Rat (Prof S. Fiala and E Fiala), 530
Liver of the African Lion : Urea Cycle Enzyme Activities of (Dr G. W. Brown, jun), 1367
Liver Cells *in situ* Potential and Resistance Measurements of Rat (O. Schanen and E. Coraboeuf), 1398
Liver Cells from Virus Susceptibility to Resistance mediated by Persistent Infection with Echovirus Type 9 Change in Chang (N Goldblum et *al*), 553
Liver DNA *in vivo* 2-Acetamidofluorene and 3-Methylcholanthrene ; Differences in Binding to Rat (M B. Sporn and C. W. Dingman), 531
Liver and from *Fusiformis nigrescens* Water-soluble Factors with Vitamin K Activity from Pig (Dr M Lev and A. W Milford), 1120–2
Liver Glycogen Content . Reciprocal Influences of the Ventromedial and Lateral Hypothalamic Nuclei on Blood Glucose Level and (T. Shimazu et *al*), 1178
Liver Glycogen and Diminished Liver-Amylase in Pancreatectomized-Enterectomized Dogs : Hypoglycaemia, Elevated (N Hiatt), 423
Liver Homogenates from Mice injected with Radioprotectors in the Presence of Pyruvate Inhibition of Oxygen Consumption of (P Ciccarone and Prof. Z. M. Bacq), 648
Liver Microsomal Lipids induced by Carbon Tetrachloride Lipoperoxidation of Rat (Dr R. O Recknagel and A K Ghoshal), 1162
Liver *in vivo* and its Possible Relevance to Mechanisms of Chemical Carcinogenesis Defluorination and Hydroxylation of 4'-Fluoro-DMAB, by Rat (J. W. Westrop and J C. Topham), 712–4
Livers Activity of Amino-laevulinic Acid Synthetase in Normal and Porphyric Human (Prof K. Nakao et *al*), 838
Livers of Rats treated with Ethionine · Control of Nicotinamide-adenine Dinucleotide Phosphate Synthesis in the (Dr J B Clark and S. Pinder), 631
Liverpool University of, Chair of Biochemistry, 783
Appointments, 1207
Living Systems Water in, 1130
Lloyd, G M , et *al* Antibody Nature of the Inhibitor to Antihaemophilic Globulin (Factor VIII), 746
Lo, A , et *al* Radioactive (Chromium-51) Heinz Bodies, 1064–6
Local Ground-level Air Concentrations of Lead-210 at Winchester, Massachusetts (B Schleien and Dr A. G Friend), 579, Erratum, 1317
Local Sign for Depth (T G R. Bower), 1081
Localization of Noradrenaline in Vesicles of Autonomic Nerve Endings Fine Structural (Dr F. E. Bloom and Prof R J Barrnett), 599–601
Localized Perfusion Cooling Spinal Cord Hypothermia by (M S. Albin et *al*), 1059
Location of the Genes controlling Penicillinase Production and Resistance to Streptomycin and Tetracycline in a Strain of *Staphylococcus aureus* . Cellular (S M. Poston), 802–4
Location of the Genetic Elements controlling Penicillinase Production in a Strain of *Staphylococcus aureus*- Chromosomal (E. H Asheshov), 804–6
Location of the Mechanism of Active Transport of Sodium across the Frog-Skin (C. A Rotunno, Dr M. A Pouchan and Prof M. Cereijido), 597–9
Location of a New Underwater Volcano : Detection and (Dr. A. C Kibblewhite), 938
Location of Spore and Vegetative Antigens of *Bacillus cereus* by means of Ferritin labelled Antibodies (R O Thomson, P D. Walker and R. D Hardy), 760
Locke, A W , et *al*. Radiolysis of Nitroalkanes, 1354

Proctor, B. A , et *al* . Dynamic Fatigue in Glasses, 730
Progesterone Biosynthesis by Equine Granulosa Cells growing in Tissue Culture (Dr C. P. Channing), 1266
Progestogen-Oestrogen Preparations : Excretion of Xanthurenic Acid in the Urine of Women taking (Dr. D P. Rose), 196
Proliferation of Human Lymphocytes in Culture (M. S. Sasaki and Prof. A. Norman), 913
Proliferation of Transplanted Mouse Bone Marrow Cells by Pre-irradiation of the Recipient . Increased (Dr N M. Blackett and S. Hellman), 1284
Promyslov, Dr M Sh , et *al* Mucolipids of the Brain in the Process of Formation of Antirabic Immunity, 1279
Pronethalol : Antagonism of Digitalis Arrhythmia by (Prof. F. G. Standaert et *al.*), 742–4
n-Propanol · Yields and Rate Constants of the Precursors of Hydrogen in the Radiolysis of (R A Basson and H J. Van Der Linde), 943
Propranolol · Optical Isomers of (Dr. R. Howe and Dr. R. G. Shanks), 1336–8
Prostaglandin from Adrenal Glands stimulated with Acetylcholine : Efflux of (P W. Ramwell et *al.*), 273
Protection of Phagocytized Bacteria from the Killing Action of Antibiotics (B. Holmes, Dr P G Quie, Dr. D B Windhorst, Dr. B. Pollara and Prof R A Good), 1131
Protection in the Radiation Chemistry of Hydrocarbons : A Correlation between Electron Affinity and (Dr. W V Sherman), 1285
Protection for Tuna, 1316
Protection Ultrastructural Aspects of Duodenal Crypts in X-irradiated Mice after Chemical (Dr J. Hugon et *al*), 749
Protection of Ultra-violet-irradiated *Bacillus subtilis* : Amino-acid (Dr. D E. Hunt), 761
Protein Intracellular Plasma (Prof. S P Kent), 1279–81
Quantitative Determination of Purine Derivatives in the Presence of Denatured (Dr E. W Busch and Dr I.-M. von Borcke), 631
Protein by the Fat Body of an Insect Sequestration of (Prof. M. Locke and J. V. Collins) 552
Protein causing Inclusion-body Anaemia An Unstable (R. W. Carrell et *al.*), 915
Protein Metabolism of Nerve Cells : Dependence of Synaptic Transmission on (Dr. R Elul), 1127–31
Protein Metabolism : Role of the Gastrointestinal Tract in (edited by H N. Munro), Symposium 1963, *review* by Dr. C. R C. Heard, 58
Protein and Non-protein Amino-acids : Stereochemical Basis for the Division between (Dr. P. Dunnill), 1267
Protein Patterns of *Septoria* Species · Comparative Gel-electrophoretic Investigation of the (Prof. R D. Durbin), 1186
Protein in the Presence of High Levels of Antibody : Antigenicity of Soluble (W J Herbert), 747
Protein in Replicating Animal Cells : Synthesis of Nucleic Acids and Nuclear (Dr J Seed), 993–5
Protein Sulphydryl Groups · Penicillamine Therapy for Rheumatoid Lung Disease : Effects on (Prof A Lorber), 1235–7
Protein Synthesis during the Mitotic Cycle of *Physarum polycephalum* : Polysome Patterns and (Dr C Mittermayer et *al.*), 1133–7
Protein Tracer Studies . Stable Bromine and Activation Analysis in (Prof P. Fireman et *al*), 547
Proteins : *In vitro* Distribution of Americium in Human Blood Serum (Dr. G Boocock and Dr. D. S Popplewell), 1283
High-sensitivity Polarimetry and its Application to the Study of Small Conformational Changes in (D. A Chignell and Dr. W B. Gratzer), 262–4
Non-Heme Iron (edited by A San Pietro), *review* by Dr. M. H Smith, 341
Role of the Amino-acid 'Code' and of Selection for Conformation in the Evolution of (Dr. C J. Epstein), 25–8
Proteins according to their Geometrical Patterns : Differentiation of Diffusing (A. Benaš and N Jelavić), 1069
Proteins and Hormones · Iodine-labelled (Dr A S. McFarlane and F. C Greenwood), 18
Proteins of Rats · Effect of Vitamin A Deficiency on the Incorporation of ^{14}C-Leucine into Tissue (Dr. B. S. Narasinga Rao), 306
Proteus mirabilis : Sucrose Permease of (Dr J A Smit and Prof. J N. Coetzee), 909
Proteus morganii Transduction in (Prof J. M Coetzee), 220
Protoplasts prepared by Snail Enzyme : Regeneration of Yeast (A Svoboda and O Nečas), 845
Protozoa, Sporozoa of Rodents : Coccidian Parasites (N. D Levine and V. Ivens), *review* by Dr G Lapage, 75
Proximity of Cooling Towers to Each Other . Wind Forces and the (D. J Gunn and A A Malik), 1142
Prulov, Y., et *al.* . Fresh Fall-out in Israel from the Second Chinese Nuclear Detonation, 833
Przybylski, Dr. A. : Abundance Analysis of the Peculiar Star *HD* 101065, 20–2
Pseudovacuoles in Cyanophyceae : Nature of (Prof E. G Pringsheim), 549
Psychobiological Approaches to Social Behavior (edited by Prof P. H. Leiderman and Prof D. Shapiro), *review* by T. H. Hawkins, 127
Psychology . Scientific (edited by Dr. B. B. Wolman and E. Nagel), *review* by Prof. J Cohen, 122
Source Book in the History of (edited by Prof. R J. Herrnstein and Prof. E. G Boring), *review* by Prof H J Eysenck, 69
Psychonomic Study of the Amnesic Syndrome Deranged Memory (Dr. G A. Talland), *review* by Prof. O. L. Zangwill, 126
Psychotropic Substance : Possible Implication of Myristicin as a (Dr. A. T Shulgin), 380–4
Pteridine Colour Forms in *Pieris* Butterflies : Chemical Phenotypes of (W. B. Watt and S. R Bowden), 304–6
Pulkkinen, M., et *al.* . Inhibition of β-D-Glucosiduronic Acid Conjugation by Eugenol, 739
Pullulanase · Reversible Action of (M Abdullah and Prof D. French), 200
Pulse Generation in the Topside Ionosphere deduced from *Alouette* I Data · Delayed Cyclotron (D. B. Muldrew), 471–3
Pulse Radiolysis of Aqueous Eosin (Prof. L. I. Grossweiner, A. F. Rodde, jun., G. Sandberg and Prof. J. Chrysochoos), 1154–6
Pulsed Ruby Laser Rangefinder : Observations of Power Station Plumes using a (P M. Hamilton et *al.*), 723
Pumps : Impeller (S Lazarkiewicz and Prof. A. T. Troskolanski), *review* by A. S. Thom, 74
Pupal Treatment Chemosterilization of *Aedes aegypti* (L) by (G. B. White), 1372
Purday, C , and Bow, Mrs J. M. · A Method of preparing Sperm Whale Teeth for Age Determination, 437
Purine Derivatives in the Presence of Denatured Protein Quantitative Determination of (Dr. E.-W. Busch and Dr. I.-M. von Borcke), 631
Purnell, Dr J. H , and Hughes, Dr. A. N : Reaction of Hydrogen Atoms with *Cyclo*propane and with Allene at 77°K, 255–7
Puromycin · Induction of Enzyme Activity in Pea Tissues by Animal Hormones and by (Dr. M. A. Venis), 534
Purpura, Dr. D. P., and Pappas Dr. G. D. : Distribution of Colloidal Particles in Extracellular Space and Synaptic Cleft Substance of Mammalian Cerebral Cortex, 1391
Pursey, H , Merran, P A , and Trevelyan, B. : Detection of Weak Microwave Modulation of Light, 511
Purves, Dr. David : Contamination of Urban Garden Soils with Copper and Boron, 1077
Pyridine Nucleotide-linked Alcohol Dehydrogenases : Proposed Catalytic Role for Histidine in (Dr H. J. Ringold), 535
Pyridines : Reaction of Glutarimide with Phosphorus Pentachloride to form Chlorinated (Dr. R. W Meikle and E A Williams), 523
Pyridoxal and Pyridoxamine Phosphate Breakdown by an Acid Phosphatase Preparation (M J. Andrews and Dr. J. M. Turner), 1159
Pyridoxamine Phosphate Breakdown by an Acid Phosphatase Preparation : Pyridoxal and (M. J Andrews and Dr. J. M. Turner), 1159
Pyrimidine Nucleotides by Chloroplasts : Conversion of Carbon-14-labelled Orotic Acid into (M. Joussaume and R. Bourdu), 1363
Pyrogen in Afebrile Rabbits · Demonstration of Endogenous (Dr. J N. Sheagren and S. M. Wolff), 539
Pyrogens and Monoamine Oxidase Inhibitors (Dr. K. E Cooper and Prof. W. I Cranston), 203
Pyrophosphate in Soil : Some Physico-chemical Aspects (Dr. D Gunary), 1297
Pyrrhocoris apterus : 'Paper Factor' as an Inhibitor of the Embryonic Development of the European Bug (Dr K. Sláma and Prof C. M Williams), 329
Pyrus malus · Effects of Gamma Radiation on Freeze-dehydrated Apples (Prof. C. Y Lee and Prof. D K. Salunkhe), 971
Pyruvate : Inhibition of Oxygen Consumption of Liver Homogenates from Mice injected with Radioprotectors in the Presence of (P. Ciccarone and Prof. Z. M Bacq), 648

Quantitative Determination of Purine Derivatives in the Presence of Denatured Protein (Dr E.-W Busch and Dr. I.-M. von Borcke), 631
Quantitative Importance of Water and Food as Supply for Calcium during Growth (Dr O. Van Der Borght and S. Van Puymbroeck), 791–3
Quantitative Relationship of the Rh-like (LW) and D Antigens of Human Erythrocytes (M. B. Gibbs) 642
Quartey, Dr. J. A. K., et *al.* : Haemolymph Pigments of Aphids, 395–7
Quartz : Ultrasonically induced Etching of (C. C. Connolly), 1251
Quasars—a Minority Report (J. H. Hunter, jun , S Sofia and E. Fletcher), 346–8
Quasi-biennial Stratospheric Wind Oscillation : Polar Lobe of the (F. A. Berson), 1243
Quasi-stellar Objects : On the Interpretation of the Line Spectra of (Prof. G. R. Burbridge et *al.*), 774–8
Quasi-stellar Objects and their Radio and Optical Magnitudes Relation between the Red-shifts of (Prof F. Hoyle and Prof. G R. Burbridge), 1346
Quasi-stellar Radio Sources : Magnetic Field within some (P. J. S. Williams), 285
Quasi-stellar Radio Sources in Steady State Cosmology : Distribution of (Dr D.
Quasi-stellar Radio Sources in Steady State Cosmology : Distribution of (Dr. D. W Sciama and W. C. Saslaw), 348–52
Quasi-stellar Source *CTA* 102 Search for Variations in the Flux of the (G. D. Nicolson), 611
Quarternary of the United States (edited by H. E. Wright, jun , and D. G Frey), *review* by Prof F. W Shotton, 454
Queen's University of Belfast : Chair of Microbiology, 142
Chair of Physics, 466
Appointments, 1207
Quicksand Structures in the Bedded Tuffs of Great Langdale, Westmorland (W R. Parker), 1247
Quie, Dr. Paul G , et *al.* : Protection of Phagocytized Bacteria from the Killing Action of Antibiotics, 1131
Quinidine and Related Compounds on Uptake and Release of Serotonin by Blood Platelets : Effect of (Dr. A. M. Bridges and Dr. M. Baldini), 1364
Quinidine · Effect of Reserpine on the Reactivity of Atrial and Ventricular Pacemakers to (E Nye and Dr J Roberts), 1376

Rabbit (*Oryctolagus cuniculus*) : Laboratory Rearing of the Parasitic Stages of *Boophilus decoloratus* (Koch, 1844) on the European (V. Ammah-Attoh), 43–4, 77
Rabinowitch, Dr Eugene : Explaining the Atom (Prof. S. Hecht), New Edition, *review* by Dr. T. E. Allibone, 52
Rabinowitz, Prof. Murray, et *al.* Effect of Trypsin on *Escherichia coli* and Rabbit Reticulocyte Ribosomes, 169–72
Racah Parameter B for Nickel (I.) and Cobalt (II) Compounds : Calculations of the (Dr. A. E. Underhill and D. E Billing), 834
Radar Backscattering from the Upper Atmosphere (75–160 km) detected by Optical (Dr. W. C. Bain and M. C. W Sandford), 826
Radial Distribution Functions by Elastic Electron Diffraction : Determination of (Dr. C W. B Grigson and M. F. Tompsett), 86
Radiation Degradation of RNA in Dilute Solution by Ionizing (Prof. E. C. Pollard), 1393–5
Their Relation to Growth Direct and Indirect Effects of (Prof. A. M. Cook and Dr. R J. Berry), 324
Unexpected Dose-rate Effect in the Killing of Mice by (Miss S Hornsey and Miss T. Alper), 212
Radiation on Birds : Effect of Microwave (J. A Tanner), 636
Radiation Chemistry of Hydrocarbons : Correlation between Electron Affinity and Protection in the (Dr. W. V. Sherman), 1285
Radiation Dose Fractionation and DNA Replication (Prof. W. B. Looney), 111
Radiation in *Escherichia coli B/r* growing exponentially in Minimal Medium : Site of Lethal Damage by Ionizing (Dr. R. J. Munson and Dr B. A. Bridges), 922–5
Radiation Injury in Mice · Influence of Aminoethylisothiouronium Bromide-hydrobromide and Hypoxia on Recovery from (Prof. E. J. Ainsworth et *al.*), 323
Radiation Law deduced from Stochastic Electrodynamics . Black-body (M Surdin et *al.*), 405
Radiation Lethality : a Disturbance in Cellular Kinetics : Mammalian (Dr. V. P. Bond et *al.*), *review* by Miss T. Alper, 60
Radiation and Lightning Hazards · Ionizing (Prof. J. E. Roberts et *al.*), 514
Radiation induced Leukaemia, Inhibition of, by the Injection of Haematopoietic Tissue : Study of Chimaerism (Miss V. Wallis, Dr. A. J. S. Davies and Prof P. C Koller), 500–4
Radiation Measurements in Commercial Aircraft using a Single Counter (Prof V. D Hopper and W. R. Rawlinson), 473–5
Radiation Mortality in Dogs treated with Typhoid-Paratyphoid Vaccine . Decreased (Prof E. J Ainsworth and F. A. Mitchell), 321–3

Radiation Sterilization of Food (Prof. S. A. Goldblith), 433
Radiation induced Synthesis of Ammonia from Nitrogen and Water (N Getoff), 940
Radiation and Urethane · Induction of Lung Tumours by the Action of (Dr P. J. Lindop and Prof J Rotblat), 1392
Radiation at 20 7-cm Wave-length , Measurement of the Minimum Cosmic Background (T. F. Howell and Dr J R. Shakeshaft), 1318
Radical Initiation Induction of the Cystine-hypophosphite Reaction by (O. A. Swanepoel and N J J. van Rensburg), 199
Radio Astronomy : Solar (Dr. M R Kundu), *review* by Prof. C. W. Allen, 559
Radio Emission of Gases in a High Voltage Discharge (Dr. G V. Mcgarl and Prof. J M. Marchello), 1214–7
Radio and Optical Magnitudes Relation between the Red-shifts of Quasi-stellar Objects and their (Prof F Hoyle and Prof G. R Burbridge), 1346
Radio Source 3C273 High-resolution Study of the (C. Hazard *et al.*), 888–91
Radio Source 3C84 Low frequency Spectrum from (S Ya Braude), 80
Radio Sources · Magnetic Field within some Quasi-stellar (P J. S Williams), 285
Strength of Cosmic (Dr. L. Gold), 927
Radio Sources measured with the One Mile Radio Telescope : Positions of (E A Parker *et al*), 22
Radio Sources in Steady State Cosmology · Distribution of Quasi-stellar (Dr D W. Sciama and W C. Saslaw), 348–52
Radio-activation Analysis : Chemical Group Separation in (D S Robertson), 1357
Radioactive (Chromium 51) Heinz Bodies (M. Martinez, A. Lo , Dr G. Cohen and Dr H Kaplan), 1064–6
Radioactive Iodine : Dextran labelled with (Dr. C R. Ricketts), 1113–5
α-Radioactivity of Human Blood (V Hasson and Dr. R. D Cherry), 591–3
Radiobiology at Harwell, 1315
Radiochemical Data Correlations for Sea-water and Coral-surface Bursts (G R. Crocker), 1028–31
Radiography · Neutron (H Berger), *review* by Prof. S E. Hunt, 123
Radiolysis of Adsorbed Hydrocarbons : Exchange Reactions in the (P J. Dyne and N H Sagert), 1153
Radiolysis of Aqueous Eosin : Pulse (Prof. L I Grossweiner *et al*), 1154–6
Radiolysis of *Cyclo*hexane : Effect of an Electron-scavenging Solute on the (Dr. R. Blackburn and Prof A. Charlesby), 1036
Radiolysis of Monomethylhydrazine (W E Shelberg), 524–6
Radiolysis of Nitroalkanes (Dr R B Cundall, A. W. Locke and G. C Street), 1354
Radiolysis of *n*-Propanol Yields and Rate Constants of the Precursors of Hydrogen in the (R A Basson and H. J Van Der Linde), 943
Radiolysis of Water Vapour . Neutralization of Hydronium Ions in the (Dr G R A Johnson and M Simic), 1356
Radionuclide Pair, Barium-140 and Lanthanum-140 · Metabolic Dissociation of the Parent and Daughter (B V. Rama Sastry), 1395
Radioprotectors in the Presence of Pyruvate Inhibition of Oxygen Consumption of Liver Homogenates from Mice injected with (P Ciccarone and Prof Z M. Bacq), 648
Radiosensitivity : Cellular Control Systems and (J. S. Orr *et al*), 699
Radium-226 in Humans and Biota of the Arctic Natural Levels of Lead-210, Polonium-210 and (Dr. R B Holtzman), 1094–7
Radley, M E. : A Second Gibberellin-like Substance in Immature Barley Seed, 969
Ragge, Dr David R : Grasshoppers, Crickets and Cockroaches of the British Isles, *review* by Sir Boris Uvarov, 63

Reserpine on the Reactivity of Atrial and Ventricular Pacemakers to Quinidine : Effect of (E Nye and Dr. J Roberts), 1376
Residuals . Azimuthal Variation of U S Station (Dr. J R Cleary and Dr. A. L. Hales), 619
Residues in the Irish Environment Pesticide (J F Eades), 650–2
Residues from Organic Solvents showing Gibberellin-like Biological Activity (Dr D E Briggs), 419–21
Resistance Measurements of Rat Liver Cells *in situ* . Potential and (O Schanne and E. Coraboeuf), 1390
Resistance mediated by Persistent Infection with Echovirus Type 9 · Change in Chang Liver Cells from Virus Susceptibility to (N. Goldblum et *al.*), 553
Resistance to Stem Rust and the Concentration of a Glucoside in Wheat · Correlation between (M A El Naghy and Prof. M Shaw), 417
Resistance to Streptomycin and Tetracycline in a Strain of *Staphylococcus aureus* · Cellular Location of the Genes controlling Penicillinase Production and (S M Poston), 802–4
Resonance Phenomenon observed by the *Alouette* Satellite . Remote Cyclotron (E L Hagg), 927–9
Resources Best Use of Economic (L V. Kantorovich), *review* by Prof K. J. W Alexander, 70
Respiration of Cardiac Muscle *in vitro* Action of Mecholyl on the (J Kozák and A. Rusnák), 636
Respiration by Oligomycin Inhibition of Pollen (Prof D. B Dickinson), 1362
Respiration in Yam Tuber Tissue (Prof. D G. Coursey, L E Fellows and Prof C B Coulson), 1292
Respiration of Young *Pinus* Seedlings · Influence of Herbicides on (S Sasaki and T T Kozlowski), 439
Respiratory Activity of Rat Intestinal Mitochondria (L E A. Symons), 422
Respiratory Changes during Electrical Stimulation of Rhinencephalic Structures in the Foetal Guinea-pig (Prof R M. Bergstrom, J I Hirvonen and L. K J Karlsson), 1176–8
Respiratory Disease Efficacy of 'Viractin' in preventing (Dr D. A J. Tyrrell et *al*), 386
Respiratory Uncoupling by 2,4-Dinitrophenol Insensitivity of Phytochrome Decay *in vivo* to (M O. Bradley and Dr W S Hillman), 838
Response Attentional Factor in Delayed (Dr S. N Cianci), 225
Response to Cercal Stimulation recorded in the Cricket Brain (H Dingle and S. S Fox), 1050
Response to Injury : Effect of Environmental Temperature on the Metabolic (Miss R M Campbell and Sir David Cuthbertson), 206
Response of the Isolated Atria of Guinea-pigs to Tyramine and Possible Significance of β-Hydroxylation : Restoration of the (Dr. B Bhagat, L. Gray and N. S Dhalla), 823
Response of *DBA/1* Mice to Vaccinia Virus Inhibiting Effect of Increasing Bodyweight on the Lethal (M L Duran-Reynals), 332–4
Response to Stress in Man Growth Hormone Secretion in (F. C Greenwood and J Landon), 540
Response to a Sudden Increase of the Dose : Antibody Inhibition by a Minimal Dose of Antigen and (J Gras and M Dalmau), 430
Response to Vitamin D in Adrenalectomized Animals (Dr. E. Czarnowska-Misztal, Dr J E Zull and Prof H. F DeLuca, 96
Ressler, Dr Newton, Olivero, E , Thompson, Dr G R , and Joseph, Dr. R R. Investigation of Ribonuclease Isozymes by an Electrophoretic Ultra-violet Method, 695–8
Ressler, Dr N , and Tuttle, C. Significance of Sub-bands of Lactic Dehydrogenase Isozymes, 1268–70
Restriction of DNA Template Activity in Chromatin is Organ-specific (Prof. J Paul and R S. Gilmour), 992
Results Presenting the (Dr. J H Wiegand), 974
Reticulocyte Ribosomes Effect of Trypsin on *Escherichia coli* and Rabbit (Dr R. Zak et *al*), 169–72
Reticulum Fragments isolated from Rat Liver Structural Aspects of Polyribosomes and Endoplasmic (E. L. Benedetti et *al*), 1156
Retina Acetylcholine and Choline Acetylase in Squid Giant Axon, Ganglia and (Dr. P Rosenberg et *al*), 858
Biochemistry of the (edited by C. N. Graymore), *review* by Dr. M V. Riley, 1088
Mach Bands Quantitative Studies on Neural Networks in the (Dr F. Ratliff), *review* by Dr F W Campbell, 128
Retina of the Experimental Rabbit : Effect of Vitamin A Deficiency on the (Prof. A Sorsby et *al.*), 1011–15
Retinae · Subcomponents of P111 in Cold-blooded Vertebrate (M Murakami and A Kaneko), 103
Retinal Excitability : Laser Lesions Changes in (A. N Nicholson and M J Allwood), 637
Retinotoxic Action of Sodium Fluoride, Sodium Iodate and Sodium Iodoacetate · Oxidizing Agents as Potentiators of the (Prof A Sorsby and R Harding), 997
Réunion Dating Geomagnetic Polarity Epochs in (Dr. F. H. Chamalaun and Dr I. McDougall), 1212–4
Reuter, A , and Kennes, F. . Strain and Sex Dependency of Pre-albumin in Mice, 745
Revans, Prof R W. Science and the Manager, *review* by R Brightman, 345
Reynolds, D G. Infection of *Culex fatigans* with a Microsporidian, 967
Reynolds, E. : A Silver-110*m* Contamination in Scintillation Detector Shielding, 615
Rhesus Monkey Infants : Effects of 6-Day Maternal Deprivation on (R A Hinde et *al*), 1021–3
Rhesus Monkeys : Intestinal Villi in (A. K Sehgal et *al*), 972
Rheumatoid Lung Disease Penicillamine Therapy for (Prof A Lorber), 1235–7
Rhinencephalic Structures in the Foetal Guinea-pig Respiratory Changes during Electrical Stimulation of (Prof. R. M. Bergstrom et *al*), 1176–8
Rhodes, Buck A , and Wagner, jun , Prof. H N. · Are Iodotyrosines Normal Constituents of Plasma ? 647
Ribonuclease and Deoxyribonuclease Activities by Substrate Film Methods : Demonstration of (Dr R. Daoust), 1077
Ribonuclease : Dry Thermal Inactivation of Trypsin and (P. F Mullaney), 953
Ribonuclease Isozymes by an Electrophoretic Ultra-violet Method : Investigation of (Dr N Ressler, E Olivero, Dr. G. R Thompson and Dr. R R. Joseph), 695–8
Ribonuclease from Ribosomes · Separation and Recombination of Ribosomal (P. L. Schell), 1157
Ribonucleic Acid Base Composition in Subcellular Fractions of Pine Pollen (*Pinus ponderosa* Law) (Prof. R G. Stanley and Andrew W. G Yee), 181–3
Ribonucleic Acid in Dilute Solution by Ionizing Radiation : Degradation of (Prof. E C. Pollard), 1393–5
Ribonucleic Acid in *Escherichia coli* B after X-irradiation.: Breakdown of (I. Pecevsky and B Miletic), 325
Ribonucleic Acid by Human Chromosomes and a Possible Mechanism of its Repression Synthesis of (S. Fujita, O Takeoka. H. Kaku and Y Nakajima), 446
Ribonucleic Acid · Nuclear Ribonucleoprotein Particles containing Messenger (O P Samarina et *al.*), 1319–22
Ribonucleic Acid Polymerase Activity in Extended and Contracted Chromosomes (Y. Hotta and Prof H Stern), 1043–5
Ribonucleic Acid-storage Inclusions of Freshwater Sponge Archaeocytes (Dr J R Simons and Miss L Muller), 847
Ribonucleic Acid Synthesis in Mouse Skin by Actinomycin *D* and 7,12-Dimethylbenz[α]anthracene Inhibition of (Dr. W G. Flamm, Dr W B Counts and Dr M. R Banerjee), 541–3
Ribonucleic Acids · Herpes Virus Specified (J Hay et *al.*), 387–90
Ribonucleoprotein Particles containing Messenger RNA Nuclear (O P Samarina et *al*), 1319–22
Ribosomal Ribonuclease from Ribosomes : Separation and Recombination of (P L Schell), 1157
Ribosomes . Effect of Trypsin on *Escherichia coli* and Rabbit Reticulocyte (Dr R. Zak et *al*), 169–72
Separation and Recombination of Ribosomal Ribonuclease from (P L Schell), 1157

REDRESSING THE BALANCE

PERSUADING young people to go in for science and technology is an essential part of the management of a modern economy. For what shall it profit a nation if it has a sound external balance of trade, a steady growth of industrial production and stable prices, but lacks assurance that the future will be sustained by plenty of scientists and engineers? This is the train of thought which led the British Government to take fright when it became known a year ago that the places available at universities were not being filled for lack of would-be students of good quality. One immediate result was the committee under Dr. F. S. Dainton to enquire into the "Flow of Candidates in Science and Technology into Higher Education". The committee has now issued an interim report (Cmnd. 2893, H.M.S.O., 3*s*.) mapping out a programme of research for several years ahead. In time, it is now plain, there will be much better statistical information on which to base decisions about the strategy of higher education. On present form, however, it is less certain that the committee will provide compelling answers to the most pressing of the questions it has been asked.

An objective study of what is meant by vacancies at British universities is nevertheless a good beginning. If the universities could have found room for 1,000 or so extra students in science and technology in each of the past two years, this is in part, at least, a measure of the speed at which they have been growing. Between 1962 and 1965 the recruitment of undergraduates in science and technology increased sharply, in response to the Robbins Report. If the vacancies at the universities were the only signs of discontent, it might not be surprising that demand for undergraduates outstripped supply. Indeed, there is something to be said for reminding the universities that good undergraduates are an asset to be sought for and then treasured. Already the talk of vacancies may have stimulated some university departments to make themselves more attractive to good potential students, which is an unexpected gain.

The vacancies at the universities are unfortunately only part of the proof that something is wrong. Departments in the humanities have also grown quickly, and yet have had to turn away good students. Ironically, a programme of university expansion intended in part to provide more scientific and technological skill has first of all succeeded in producing more humanists. Similar tendencies are apparent in the schools. It is true that there is still a steady growth of the numbers following courses in science and mathematics in the years immediately before going on to higher education, but these subjects occupy a steadily diminishing proportion of the efforts of the sixth forms in British schools. As a proportion of the total, passes in science subjects in the advanced level examinations have decreased steadily since 1958. By contrast, there has been a rapid growth of interest in studies such as economics. Within the traditional school science curriculum, biology has prospered but the number in chemistry at advanced level has absolutely decreased. In the competition to attract the growing intellectual interests of young people in Britain, the humanists (and the economists) have the edge.

The statistics in the interim report have mostly been collected from familiar sources, and thus do little to clarify the causes for the shift of interest among young people. That is no surprise, for it is too soon to expect a thorough study. What matters is the programme of research now promised. By studying the transition from school to university over a longer period, the committee will help to decide whether the present disenchantment with science and technology is a delayed response to the acute shortage of university places in these subjects only a few years ago. More information about the academic qualifications and the professional training of teachers in schools may suggest ways of recruiting good teachers in the sciences, though it is likely that the demands made by industry for scientists and technologists will always make it hard to recruit as many highly qualified people as the schools would like. (By the same token, British schools have scarcely begun to exploit the tendency of industrial scientists and engineers to look for other jobs after a decade or so at a laboratory bench.)

The committee also plans a number of more difficult qualitative studies. It will, for example, study what is known about the selection of students by universities and the choice of specialties by students. The examining authorities, recently much maligned, are likely to be further harassed by statistics which suggest that it is harder, and sometimes more like a lottery, to pass an examination in science than in some other subjects. The interim report declares that the committee will study selection procedures so as to see "that individuals with the necessary qualities of character, imagination and originality for careers in science and technology are not excluded on purely academic criteria" and, in the same spirit, it is to analyse "mathematical attainments in the population and their possible relation to premature and irrevocable decisions against science and technology". Obviously there will be fur flying among the custodians of university entrance requirements. Finally, to round off this ambitious programme of research, the committee will study the qualities needed to make a good teacher, the importance of advice about careers to students leaving school, and the influence of schemes for curriculum development (and reform) in making science seem more (or less) attractive as a career. There is plenty of meat in these proposals. The final report is plainly and understandably some way off.

What, in the meantime, is to be done? Happily, there are signs of progress on issues which the Dainton Committee plans to study. The importance of recruiting good teachers and the need to help the old hands keep up to date (at no cost to themselves) is being recognized. Curriculum development may yet do wonders, especially by making science seem to young people still at school the modern equivalent of what the humanities were to the Rennaissance. There is even talk of liberalizing

entrance requirements to universities, and the promise of some progress. All this will help, but it may not—unfortunately be enough. For it is possible that the causes of the drift from science in the schools are closer to the foundations of the British education system, and lie in the unique pattern of specialization in the years before university. It may be significant that science holds its own with the humanities in the early years at school, and that it loses ground when young people are expected—at 16 or 17—to make an almost final choice. May not some potential scientists be protesting that they would first like to speak French more fluently, and to learn what Keynes was all about? And may they not be right? In other words, a proper study of the disaffection of potential scientists demands a study of the balance of the curriculum—at schools and, to some extent, at university. Even if such a study should raise the prospect of a four-year undergraduate course, the Dainton committee should not flinch from adding this to its already overcrowded brief.

BY RAIL TO FRANCE?

MR. STANLEY RAYMOND, the chairman of British Rail, may have spoken more wisely than he knew when he said, on March 14, that if the digging of a tunnel beneath the English Channel did not begin this year, it had better be abandoned altogether. For the case for the Channel Tunnel is no longer overwhelming. If the tunnel could have been built at the end of the nineteenth century, it would no doubt have been a great boon to Britain and to France. But now, as Mr. Raymond seems to feel, the passage of time is against it. Other ways of crossing this narrow strip of water have become progressively more efficient and attractive, while the consequences of the existence of a tunnel have become more disconcerting. Hovercraft may be cheap, fast and flexible to use. The claims of the bridge-builders strengthen as the years go by. Then in Kent and in the Pas de Calais town and traffic planners are already wondering how they will manage if a tunnel should be built. The problems of driving trains through narrow apertures at the speeds now being dreamt of have yet to be faced. And there is no knowing that a single tunnel could accommodate the growth of travel across the English Channel since the last traffic survey, and the extrapolation based on it, nearly a decade ago.

These, of course, are not the doubts that worry Mr. Raymond. He is faced with the need to provide for the potential travellers and for the freight which seems to increase alarmingly in volume whenever the prospects of Britain joining the European Economic Community brighten, however fleetingly. Should British Rail put its faith in a tunnel, or should it buy new ships or hovercraft instead? That, on the face of it, is a commercial decision to be made. In reality, however, the problem is more complicated. In spite of all the surveys which have been carried out, the tunnel remains something of an unknown quantity. How much would it really cost? How effectively would the undoubted virtues of a through journey by rail persuade users to fight their way to the loading points? And, if it were successful, what would be the social costs in congestion and in disturbance of funnelling a large proportion of an important traffic through a single route? Matters like these have not yet been studied with the care that they deserve. The case for yet another survey is overwhelming. It is true that repeated surveys are frequently no more than means of postponing important decisions, but they also share some of the rare benefits of the trials by ordeal popular in the Middle Ages. If, indeed, the delay of one more year should be intolerable, the Channel Tunnel had better be abandoned now, before it is begun.

PHYSICS—GROWTH OR DECAY?

THE threat of unaccustomed lack of funds for research in physics in the United States is one of the spectres to emerge from a report now published by the Physics Survey Committee of the U.S. National Academy of Sciences*. "For the first time in the history of physics in the United States, budgetary limitations threaten our ability even to sustain productive continuing activity in many segments of physics." Almost literally, professional physicists are wondering where the next accelerator is to come from.

The Physics Survey Committee is one of several committees set up two years ago by the Committee on Science and Public Policy of the National Academy. The intention is to make a comprehensive and systematic survey of the condition of science and its need of support. (The committee on chemistry has already reported (*Nature*, 209, 541; 1966).)

The sense of discontent in what the report has to say about federal support for physics springs chiefly from recent fluctuations in the money available and from changes in policies for spending it. "When sharp variations occur—either upward or downward—from a steady growth rate in financial support for physics, serious difficulties can occur."

The Committee says that when funds suddenly become scarce, the first research to suffer tends to be the comparatively unspectacular work at universities by post-graduate students in training. The "high visibility" laboratories, as they are called, "tend to pass a disproportionately large share of the cut-back on to smaller projects, thus striking a disproportionately large blow at the training of new scientists". The Committee also argues that at times of sudden shortage, new researchers suffer more than established men; according to figures from the U.S. National Science Foundation, only 7 per cent of the proposals for research by new investigators in 1963–65 were granted. The committee also protests at the danger that unexpected surpluses can lead to the construction of facilities which cannot be fully used, and at the imbalances that can arise when government agencies impose external (and sometimes arbitrary) limits on the proportions of available funds to be spent on services and on materials.

But how much money should there be? The Committee acknowledges that any answer to this question must be hedged with qualifications. It also proclaims that "physics does not seek to grow without limit. . . . Science is clearly becoming a more extensive part of modern life, but science in general and physics in particular do not threaten to consume the gross national product". Briefly, however, the Committee would like to see an annual growth rate of 16 per cent between 1963 and the end of this decade—a figure which it modestly compares with a rate of growth of between 20 and 30 per cent in the late fifties and early 'sixties.

* *Report on the Present State of U.S. Physics and its Requirements for Future Growth*, National Academy of Sciences, Washington, D.C. 5[illegible]

Reality has already fallen short of expectation. The Committee says that between 1963 and 1964 the increase of funds for physics (excluding certain amounts spent by the National Aeronautics and Space Administration on astronomy) was roughly 7 per cent. The National Science Foundation bears out this estimate for university research, and also suggests a similarly modest increase between 1964 and 1965. Hopefully, the Physics Survey Committee has calculated that in the remaining four years of the decade, the annual growth of funds for research in physics should be 21 per cent.

Arriving at these estimates of future needs has involved a study of current research in separate branches of physics which is itself of absorbing interest. Each of six sub-committees was given a part of the subject to investigate, while a seventh was made responsible for theoretical physics of all kinds. The terms of reference asked for an assessment of the then level of activity in each sub-field of physics, in money and in men. The committees were also asked to study the production of doctorates and the balance of activity between government, industry and universities. Finally, they were presented with a group of questions intended to identify the intellectual goals of current and impending research, and to estimate the resources needed to attain these ends.

The following are the chief recommendations of the panels:

Astrophysics, Space Physics, Cosmic Rays and Gravitation Physics

The sub-committee asks for a recognition that "the development of new techniques does not render the old ones obsolete", which is intended to imply that vigorous space research must be accompanied by a commensurate programme on the ground. Space telescopes (in all regions of the spectrum) are expensive, so that ground-based instruments should be used whenever the conditions of seeing permit. The sub-committee also points to the way in which radioastronomy has placed a strain on the few optical instruments capable [illegible] objects possibly associat[illegible] sub-committee endo[illegible] Whitford Comm[illegible]

ators, and the sub-committee has made a valiant attempt to show some of the predictable ways in which such machines could be used. Thus it would like to see detailed quantitative studies of the new short-lived resonance states of the elementary particles, in the hope of finding new symmetries or new quantum numbers. The study of weak interactions by inverse β-decay, using beams of neutrinos produced by accelerators of high intensity operating at energies in the GeV range, is an important need. Because a substantially more powerful accelerator could not be in operation until 1973, the sub-committee commends the devices of storage rings for atomic particles, the improvement of existing machines, and the building of a 'meson factory' (also supported by the nuclear physicists) for producing beams of mesons at high intensity by means of protons accelerated to between 500 MeV and 800 MeV.

This sub-committee also argues that high-energy physics is a valuable means of training Ph.D. graduates, now being produced at a rate of 140 a year. The total annual cost of high-energy physics works out at 150,000 dollars a year for each post-doctoral physicist in the field. Expenditure increased from 125 million dollars in 1963 to 147 million dollars in 1964. If the sub-committee has its way, the total cost of high-energy physics will be 500 million dollars in 1975. Among the new projects the sub-committee would like to see are the new 200-GeV proton accelerator, on which a decision is expected in the coming U.S. financial year; the improvement of the synchrotrons at the Argonne and the Brookhaven National Laboratories, and an improvement programme for the linear accelerator at Stanford; the building of magnetic rings for storing electrons and positrons; and a design study for a proton accelerator in the energy range 600 GeV–1,000 GeV.

Nuclear Physics

The sub-committee directs attention to the uses that may be made of mu-mesons in defining the nucleon structure [illegible] nuclei once sufficiently energetic and intense beams [illegible] available. It also boasts of the usefulness of such

question with the phrase "the borderline between science and technology".) The sub-committee expects that expenditure on solid-state research will double between 1963 and 1969, with the U.S. Government and private sources (industrial and university) sharing the cost almost equally.

Theoretical Physics

This sub-committee is clearly pleased to be able to imply that theoretical studies—as such—are cheap. Government support for theoretical research in the United States is estimated to have doubled between 1959 and 1964, when it reached 8·45 million dollars. The sub-committee is excited by the possibilities in the physics of elementary particles, in many-body systems (including plasmas), and in solid-state and low-temperature physics.

Classical Physics

This sub-committee has a worthy tale to tell, particularly in statistical mechanics and mechanics—particularly hydrodynamics and the like. It remains a surprise that 6 per cent of physicists in the United States work in acoustics. Optics has been enormously stimulated by space research.

The outcome of the separate studies (together with that of the committee on applied physics) is summarized in Table 1.

These figures will undoubtedly be the basis for discussions between physicists and government agencies in the United States on the financing of future work. In reality, however, they are more than a rapacious shopping-list. The Physics Survey Committee has also made recommendations to professional physicists and to universities and other institutions of higher education. Thus members of the profession are asked to pay more attention to the problems which the Committee itself has done much to define. The implications of this study for universities in the United States are understandably far-reaching.

Table 1. UNITED STATES EFFORT IN BASIC PHYSICS, PRIVATE AND FEDERAL GOVERNMENT COMBINED

	New Ph.D. graduates 1963	Total spending 1963 (millions of dollars)	Estimated spending 1969 (millions of dollars)
Astrophysics, etc.	50	59	105
Atomic, etc.	118	17	52
Elementary particles	110	125	330
Nuclear physics	154	69	99
Plasma physics	35	50	100
Solid-state	226	173	380
Theoretical, etc.	*	4	8
Totals.	693	497	1,074†

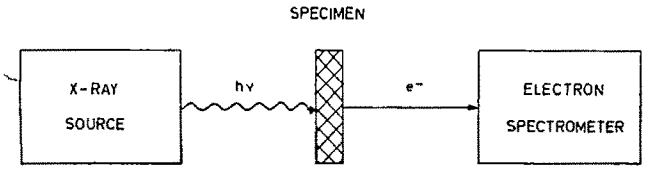
* Ph.D. graduates assigned to other categories.

† 55 million dollars has also been estimated for 'intermediate' energy physics, which would bring the total to 1,129 million dollars.

The Committee is principally concerned with the demand for university teachers and researchers because of the continued expansion of the universities, and because post-graduate education is being more widely regarded as a supplement to a first degree. Based on a model of the balance between different layers in the educational pyramid, the Committee looks forward to—and asks for—a sustained growth of university physics in the years ahead.

Only time, of course, will show how all this turns out. At some stage the National Academy's Committee on Science and Public Policy is going to have to put the claims of the several subject committees alongside each other, and then go through the motions of harmonizing them. The outcome of that quasi-judicial procedure will be an important precedent even if the Federal Government does not take all the advice that it is being offered on the rate at which expenditure should grow.

ELECTRON SPECTROSCO[illegible] BINDING
[illegible]NG



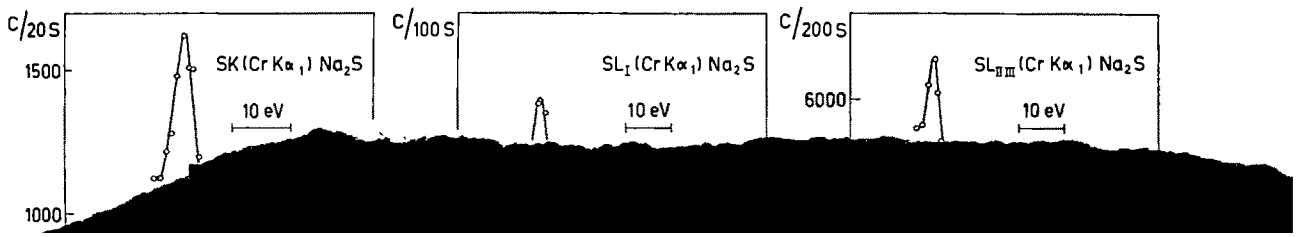


Fig. 1. The principle of the ESCA-method. Photo and Auger electrons obtained from an irradiated specimen are analysed in an electron spectrometer

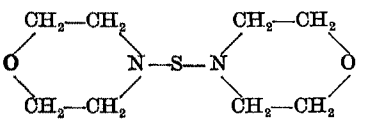
where E_b is the electron binding energy. E_b assumes different values for different electronic shells and it is not solely a property of the atom for it is also to some extent dependent on the chemical state of the atom, that is, on the arrangement of neighbouring atoms. Therefore, the energies of expelled photo electrons may be slightly shifted as the chemical state is changed. Inasmuch as present-day techniques in electron spectroscopy make it possible to observe and measure these shifts of X-ray-produced photo electron lines, the new method makes it possible to throw some light on the finer details of the electronic structure that are connected with chemical binding. Previous attempts in this direction, made in the 1930's by H. R. Robinson and his colleagues[6], have met with only limited success. Fig. 1 shows in schematic form the experimental arrangement that we have used. Two high-precision electron spectrometers are utilized, one spectrometer of the iron-free double-focusing type and one semi-circular iron-cored spectrograph. The X-ray source used with this latter instrument is equipped with a bent crystal monochromator and detection is accomplished by counting the electron tracks in a photographic emulsion. The instruments are described in detail in refs. 7 and 8.

In the experiments reported here we extended our earlier measurements for the element sulphur[3]. The procedure was first to find a relationship between the spectral position of a photo electron line and the oxidation state of the atom from which photo electrons had been expelled and then to use this information for determining the oxidation state of the same element in some other chemical compounds.



Two sets of sulphur compounds were chosen in which the oxidation number of sulphur varied from 2− to 6+, namely, the sulphide, sulphite and sulphate of sodium and potassium respectively. The zero state was represented by sublimed sulphur. Photo electron lines were recorded from the K, L_{I} and $L_{\mathrm{II,III}}$ shells of sulphur in the different compounds. Copper and chromium $K\alpha_1$ radiation was used for the production of photo electrons. Electron spectra for sodium sulphide and sodium sulphate are shown in Fig. 2. The lines of these electron spectra are very sharp (the half-width being about 5 eV) and the peaks can be located to within a fraction of an eV. On the low-energy side there is a distribution of electrons that have suffered energy losses on emerging from the source. The losses occur in discrete amounts, typically of the order of 10 eV. With the high resolution achieved in the electron spectrometer the undisturbed peak may be separated from the distribution of energy-degraded electrons. The lines of Fig. 2 were recorded with the iron-free double-focusing instrument and the intensity of the electron lines is high for the K shell with a net counting rate at the peak of the strongest line of 6,000 counts per min.

As seen in Fig. 2, the electron lines are shifted by several eV when going from the 2− to the 6+ oxidation state of sulphur. Many spectra were recorded from each compound and sources were prepared in different ways and on different backings. All the substances are poor electric conductors. One may therefore expect the sources to become charged, especially if insulating backing materials are used. Such effects have been observed for β-ray sources in nuclear spectroscopy[9]. In our experiments

when the source was continuously exposed to X-radiation the situation was quite different. Even in our first experiment with an insulating tape as a backing material[4] the charging of the source was found to be negligibly small. A possible small effect of this kind of about 1 V was in some cases observed if the thickness of the sample was more than a few tenths of a millimetre and with insulating backing material. Most sources were, therefore, made by dissolving the compounds and letting a droplet of the solution evaporate to dryness *in vacuo* on an aluminium backing. For such thin sources on a metallic backing no charging was observed.

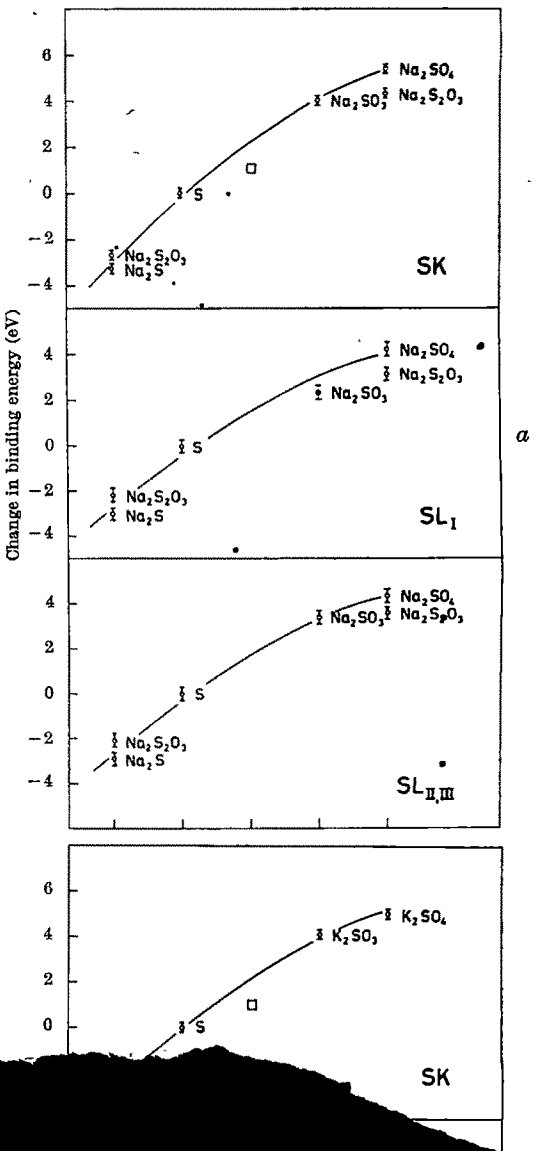


Fig. 3 shows the shifts of the binding energies obtained for the K, L_{I} and $L_{II,III}$ electrons of sulphur for different oxidation numbers. Fig. 3*a* shows the results obtained for compounds with sodium as a cation and Fig. 3*b* with potassium as a cation. Error bars indicate reproducibility errors and lines have been fitted to the experimental points as an eye guide. In the diagrams for the K shell we have, somewhat arbitrarily, included a result obtained for di-(4-morpholino)-sulphide:

which may be taken to represent the 2+ state of sulphur. Some interesting details contained in the diagrams may be noted:

(1) The electron binding energies of inner shells increase with increasing oxidation number. (2) All three levels K, L_{I} and $L_{II,III}$ have an energy shift of about 1 eV per degree of oxidation, that is, on a relative scale the shifts are larger for the L shells than for the K shell. (3) The shifts are somewhat larger for the K-level than for the L-levels. (4) The shifts are about the same for the set of compounds with potassium as a cation as for the compounds with sodium as a cation. The sulphide shifts, however, differ by as much as 1 eV.

These observations can be compared with those made on the shifts of X-ray emission lines (see, for example, ref. 10). It is then found that X-ray data are consistent with the electron spectroscopic data, but it must be borne

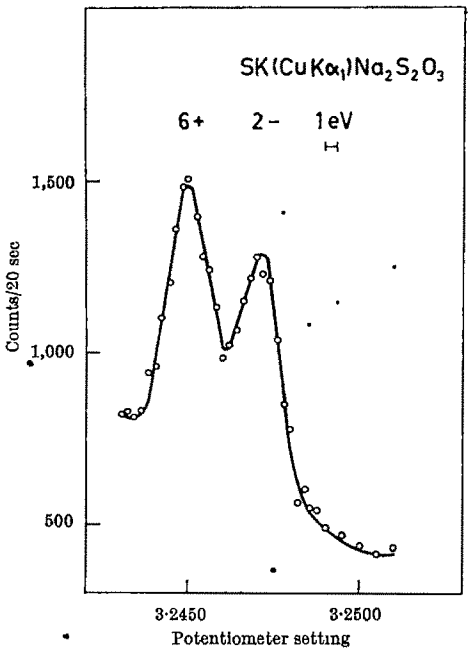

Fig. 4. Photo electron spectrum of the K shell of sulphur in sodium-thio-sulphate, $Na_2S_2O_3$. Two lines are obtained corresponding to the oxidation numbers 2− and 6+

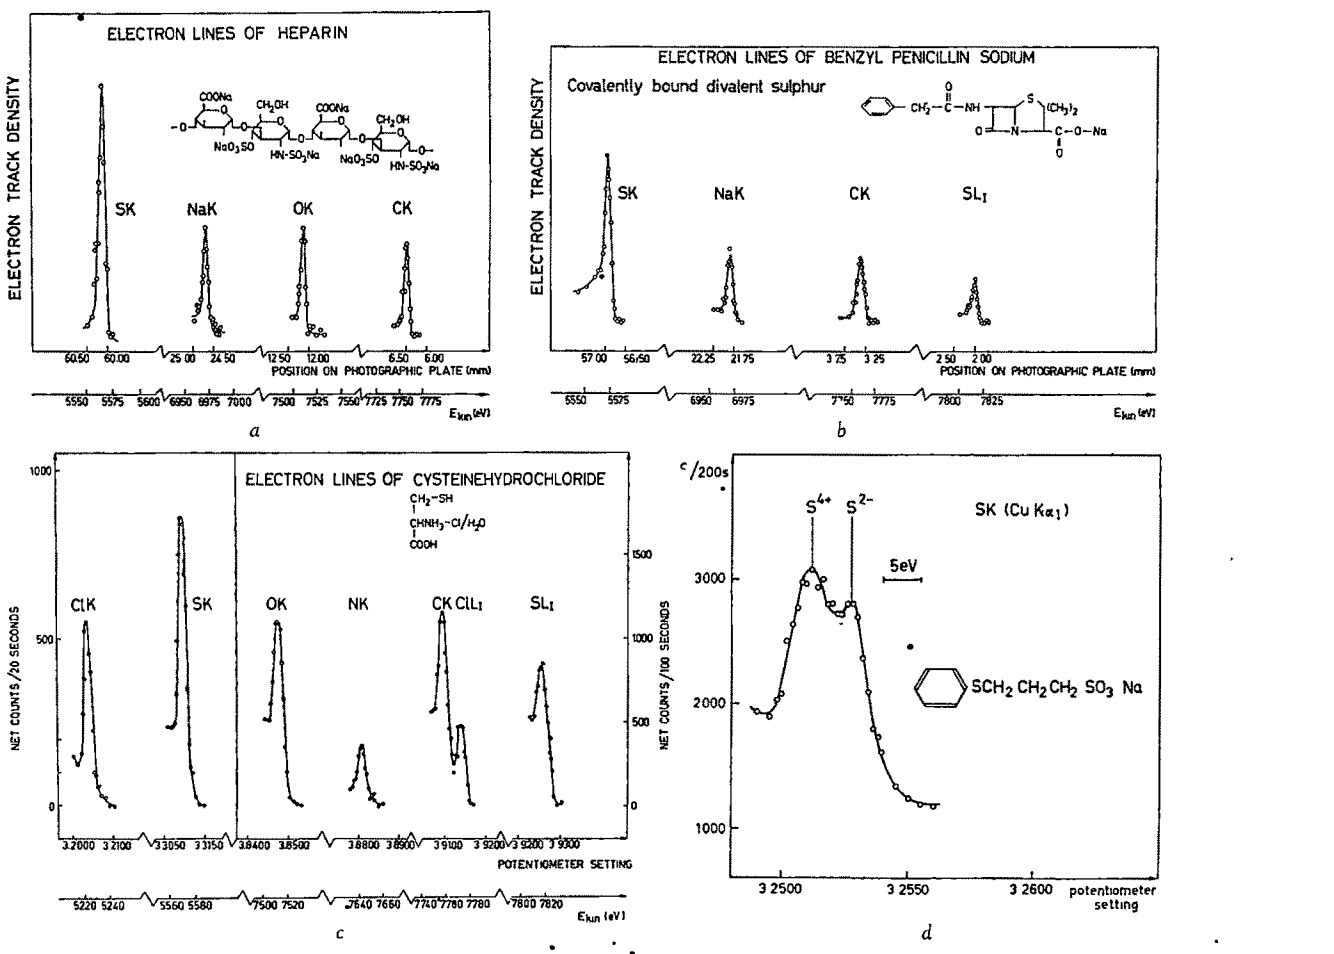
equation (2) equal to the mean radius of the $3p$ orbital in sulphur we obtain $r = 1{\cdot}0$ Å from the wave functions calculated by Herman and Skillman[11] and an energy shift of the inner levels of 14 eV per degree of ionization. The observed shifts are about 1 eV per oxidation number and a change in oxidation number of one unit would then correspond to a charge in atomic change of about 0·07 units, that is, would correspond to 0·07 electrons removed to infinity. More refined calculations of the energy shifts of inner levels due to removal or addition of valence electrons have recently been made by I. Lindgren with a modified Hartree–Fock–Slater technique[12]. For low degrees of ionization he obtains an energy shift of 12 eV per degree of ionization, and also finds a somewhat larger shift for the K shell than for the L shells. Based on the very simple free-ion model the theory is, of course, still far from being complete.

Electron binding energies determined with the electron spectroscopic method have the Fermi-level as a reference level[13]. A possible explanation of the observed shifts could be that the Fermi-level is shifted to different positions in the forbidden gap between the valence and conduction bands or that all levels except the Fermi-level are shifted near the surface as a result of the formation of surface states, the shifts being different in different compounds. This explanation may be rejected if one finds different energies of an electron line from atoms of an element in different molecular positions. In fact, this observation has been made. One example is given in Fig. 4 which shows the photo electron spectrum of the



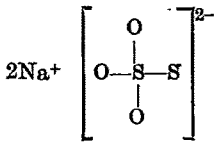


Fig. 5. Electron spectra from complex organic compounds. (*a*) Electron spectrum of heparin with lines from sulphur, sodium, oxygen, and carbon. The K shell binding energy for sulphur corresponds to an oxidation number of 6+. (*b*) Electron spectrum from benzyl penicillin sodium with covalently bound divalent sulphur. Lines are also obtained from sodium and carbon. (*c*) Photo electron lines from an amino-acid, cysteinehydrochloride. Fine signals are obtained from oxygen, nitrogen, carbon, chlorine, and sulphur. (*d*) Electron spectrum of the K shell of sulphur in sodium-thio-sulphonate with two lines corresponding to the oxidation numbers 2− and 4+

sulphur K shell in sodium-thio-sulphate with copper $K\alpha_1$ radiation. Sodium-thio-sulphate, $Na_2S_2O_3$, has the following structure:

with two sulphur atoms in different chemical positions with oxidation numbers 2− and 6+. Two lines are obtained in the electron spectrum. The peak positions of the thio-sulphate are consistent with the graphs of Fig. 3 which give relationships between the spectral positions of photo electron lines and the oxidation number of the sulphur atom.

Oxygen was present in the crystal water, as an adsorbed layer on the surface, and as a constituent of the sulphite, sulphate and thio-sulphate ions. Conceivably, the oxygen atoms in these different positions could have slightly different electron binding energies and one could expect a broadening or even a splitting of the photo electron lines of oxygen. No such effect was observed and the oxygen K photo electron line could therefore be used as an internal reference line in each sample. Thus, further evidence was obtained that the observed shifts of the sulphur-levels do not result from shifts of the Fermi-level or from the formation of surface states.

We have also made measurements on complex organic molecules. Fig. 5 shows electron spectra obtained from the organic compounds heparin, benzyl penicillin sodium, cysteinehydrochloride and sodium 3-phenylthiopropane-sulphonate, all of which contain sulphur as a constituent. The heparin and penicillin spectra of Fig. 5*a* and 5*b* were obtained with the semi-circular spectrograph and electron track counting technique, and the spectra of Fig. 5*c* and 5*d* were recorded in the double-focusing instrument. Not only the sulphur lines were recorded but also electron lines from other elements in the compounds. Most of these elements have low atomic numbers and cannot readily be seen in X-ray spectra. With the aid of the graphs of Fig. 3 the oxidation number of the sulphur was estimated at 6+ for heparin, 2− for penicillin, and 2− for the amino-acid cysteinehydrochloride. The phenylthio-sulphonate is another example of a compound with sulphur in different chemical positions, and the electron spectrum of Fig. 5*d* has two lines from the sulphur K shell. They correspond to the oxidation numbers 2− and 4+ as one could in this case expect from the structural formula:

Many molecules are known to decompose under prolonged X-irradiation. No such effect was observed as the time of exposure was kept relatively short.

Electrons are emitted from an X-irradiated sample not only by photo electric effect but also in the Auger process. The Auger process is the radiationless alternative to X-ray emission for the de-excitation of atoms with inner shell vacancies. In a measurement of the KLL Auger spectrum of sulphur we have found that also the Auger transition energies depend on the chemical state of the atom[14]. This is illustrated in Fig. 6 for the sulphur $KL_2L_3(^1D_2)$ Auger transition in sodium-thio-sulphate. Again two lines are obtained, corresponding to the two different chemical states of the sulphur atoms. Auger spectra yield additional and complementary information to the photo electron spectra. Thus, the observed separation, 4·3 eV, of the double Auger line in Fig. 6 confirms our previous result that the K-level shift is somewhat larger than the L-level shift (see Fig. 3).

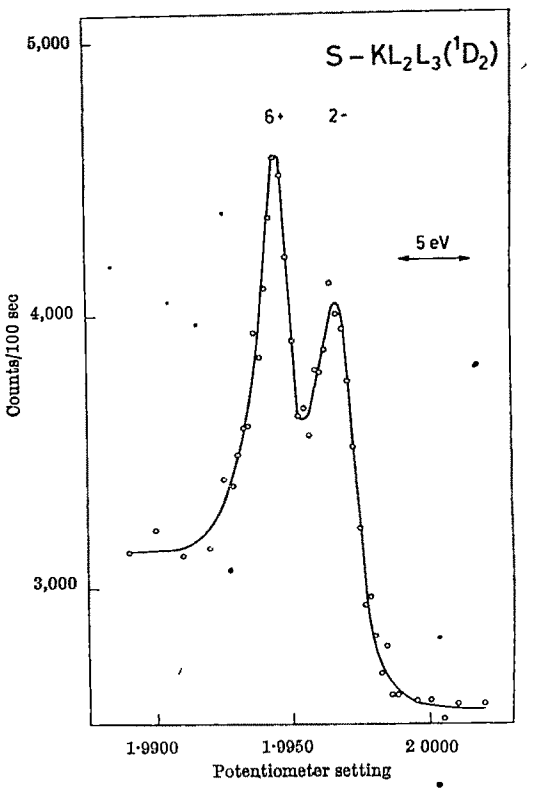

Fig. 6. The energy of an Auger transition depends on the chemical state of the emitting atom. This is illustrated in the figure by the Auger line $KL_2L_2(^1D_2)$ from sulphur in sodium-thio-sulphate. The line has two components, one for the 2− and one for the 6+ state of oxidation, and the energy separation is in agreement with the photo electron data of Fig. 3*a* for the individual levels. Finer details about chemical effects on the inner electronic structure can be obtained from Auger spectra

In addition to the element sulphur we have found chemical shifts in other elements such as phosphorus, chlorine and iodine. These shifts are also of the order of several electron volts. The results obtained so far strongly encourage further exploration of the electron spectroscopic approach to an improved understanding of the electronic structure of atoms and solids and the nature of the chemical bond.

This work has been supported in part by the U.S. Air Force, through the European Office of Aerospace Research and by the U.S. Department of Army through its European Research Office. We thank Dr. Bernt Lindberg, Pharmacia, Uppsala, for providing most of the organic compounds. We also thank F. M. Gunilla Axelson, F. M. Robert Carlsson and F. M. Ulf Ericson for valuable help with the measurements.

NEUTRON ACTIVATION ANALYSIS AND ARCHAEOLOGY

By MICHAEL J. ASHWORTH

Canadian Historic Sites Division, Ottawa

AND

THOMAS P. ABELES

Department of Chemistry, University of Louisville

ARCHAEOLOGISTS have long applied scientific techniques in their study of man's past. The first of these techniques was borrowed from geology, and is that of stratigraphy—the ordered sequence of cultural deposits. This was first noticed by the British archaeologist, Stukely, who in 1723 published the section of a barrow which he had excavated near Stonehenge. On the American side of the Atlantic, the first person to notice the phenomenon of archaeological stratification was the statesman Thomas Jefferson, also an amateur archaeologist, who in his *Notes on Virginia*, published in 1784, indicated the stratigraphical stages in the construction of a mound which he had examined.

The archaeologists of this period were ahead of their time, however, and it is only in the past 30 years or so that there has been a birth of truly 'scientific' archaeology as opposed to the indiscriminate collecting of artefacts. The onset of modern methods in British excavation came with the work at Caerleon, Monmouthshire, in 1924, directed by Dr. (now Sir) Mortimer Wheeler, while perhaps the most important contribution of science to archaeology has been the application of radiocarbon dating by W. F. Libby. Even in the past few years, there has been a marked increase in the contribution of science to archaeology, as exemplified by the recent investigations of Aitken[1] and Biek[2], and the volumes edited by Brothwell and Higgs[3], Heizer and Cook[4], and by Pyddoke[5].

Such studies can best be considered under three headings, namely, site location, dating, and artefact analysis. The first category includes aerial photography, magnetic location, resistivity prospecting, the use of the mine detector and proton and rubidium magnetometers, and the new technique of location by infra-red radiation. Dating includes the well-known method of radiocarbon dating which is now so common that there is some abuse of the technique in archaeological interpretation, and also dendrochronology, dating by magnetism, thermoluminescence, fluorine–uranium–nitrogen ratios, and also newer radioisotope decay methods. Finally, there is the field of analysis of artefacts, but this has not received so much consideration as the other two categories. The paper by Caley[6] explains the reasons for chemical analysis of archaeological materials, and this present article examines one method of analysis, that of neutron activation. It is interesting, however, first to explain the reasons for the need to analyse archaeological finds, and secondly to show why neutron activation is in many instances the best of several methods.

The most obvious reason for analysis is simply to find out what an object is made of, with all that this implies. Very often, appearances can be deceiving, and, for example, weapons have been assigned to the Bronze Age simply because they were supposedly manufactured from bronze. Recently, analysis has shown that some of them are, in fact, copper—resulting in the need for a reappraisal of this period of British prehistory. Again, even an archaeologist with expert knowledge of metallurgy would have difficulty, given a silver coin, to tell; on the basis of appearance alone, whether it contained a moderate proportion of alloy or whether it was fine silver. This is of importance in showing either the existence of refining techniques, or else in the deliberate debasement of the coinage. Similarly, from the composition it is possible to determine, especially in metals, the method of manufacture, and consequently the degree of technical competence of the culture that produced it. Metals can, for example, only be spun, cast or wrought within certain well-known compositional limits.

Carrying this one step further, the scientist can state where metallic ores occur, but it is the archaeologist who then determines the conditions of contact and commerce that brought them to the area of manufacture. It is often possible to find trace elements in an analysis that act as a 'fingerprint' which identifies the source of supply. The presence of impurities in the clay of one area, coupled with the same impurities found in the pottery of another area, would be a strong reason for postulating contacts between the two areas. More recently, it has been found that particularly for glass there was a change in composition not from one area to another, but from one period to another. Thus, simple chemical analysis can possibly be used as a method of dating[7,8]. Similarly, in Britain, as has already been mentioned, it has been found that in the Bronze Age there are several chronologically significant innovations in metallurgy, with the later period being marked by the addition of a small percentage of lead, used as a wetting agent to improve the casting.

There are many different methods of chemical analysis, but the majority of them can be disregarded, because they are destructive, and even nowadays many archaeologists are reluctant to have their finds destroyed, even though by this destruction they can learn more about them. They tend to forget, however, that the process of archaeological excavation itself, by which the objects were uncovered, is also a destructive 'experiment' that cannot be repeated.

Spectrometry has the disadvantage that it is not possible to identify elements of an atomic number lower than 12, unless the work is carried out *in vacuo*. Also the analysis relates only to a thin surface layer of the specimen which would often not be representative of the whole composition. Diffraction analysis also suffers from the limitation that it is not always possible to obtain a representative sample from an object such as coarse-textured pottery. Neutron activation analysis, however, is rapid, can be non-destructive, and is extremely accurate; however, it has the one drawback of needing the presence of a neutron source, which is usually a nuclear reactor, but which could also be a neutron howitzer. This is more than compensated for by the ability to work with very small quantities (5 mg or less) which would permit the unobtrusive removal of small samples for laboratory analysis from a museum exhibit.

The basic principles of activation analysis can be broken down into three elementary steps: the activation, detec-

tion, and final analysis. The sample to be analysed is first activated by exposure to a source of thermal energy neutrons. Being a non-charged particle, the neutron penetrates the entire sample with relative ease, and induces activity for observation not only on the surface, but throughout the artefact. If one has a large object to irradiate, and only wishes to induce activity in a small portion, and removal of any fraction of the artefact is not feasible, one may shield the majority of the sample in cadmium to prevent activation. Because the process is a nuclear phenomenon and involves only very few atoms, there is no detectable change in the appearance or chemical characteristics of the artefacts involved.

The amount of activity produced is a function of the number of neutrons that penetrate the sample (flux), the amount of each element which can be activated, and the cross-section of the element (the measure of the probability of a neutron interacting with an atom). Each element which is active emits radiation (α, β, γ) in a unique pattern. Since one is interested in all active elements, even inside the artefact, γ-rays are chosen as the type of radiation to be detected.

Basically, a γ-ray is emitted from the sample and impinges on a detector (usually sodium iodide activated with thallium) which absorbs the ray and produces a light pulse proportional to the energy absorbed. This light pulse is then picked up by a photomultiplier tube which amplifies the signal further, which then goes through additional amplification, and then to a pulse height analyser. This 'black box' contains a sorting and storage mechanism whereby it can discriminate between the different incoming pulses and store each different pulse in a separate memory bank. At the end, the memory is read and the number of counts in each bank or channel indicates the number of γ-rays of a certain energy that were detected, and thus gives an indication of how much of each element was present. There are usually 100 or more channels for storage, and by previously calibrating these with γ-rays of a known energy, not only can the amount of each element be determined, but the different energies can be identified, and thus it is possible to identify the particular element emitting the ray.

Since there are variable mechanisms by which a γ-ray can interact and efficiency may not be 100 per cent, and, since there is always inherent electrical distortion of the signals, a broad spectrum of energies is obtained, but the main peaks correspond to the γ-rays of interest. These spectra then have to be interpreted, and to facilitate the identification of elements, tables of standard spectra have been compiled. Often for quantitative measurements known standards can be run for comparison. When many elements are present the spectra may become complex, and to handle this, computer programmes have been written to resolve the components.

Because of the inherent sensitivity of activation analysis (in many instances, elements in the parts per billion region have been detected), and because of the possibility of using small samples, and due to the rapidity of the technique, with many complete analyses in an hour or less, the archaeologist now has a very powerful tool at his disposal for artefact analysis, especially since many of these analyses are completely non-destructive.

The technique of neutron activation analysis has only recently been applied to archaeology and its problems, but it is a research tool that holds much promise for the future. Several pilot studies of this method as applied to the analysis of archaeological materials have been made in the United States, Britain, France and The Netherlands. The earliest application of the method was in 1952, in France, where Ambrosino and Pindrus[9] studied coins from the collections of the Louvre. This was followed by work in Japan, where Emoto[10] used a cyclotron to detect silver in the lead tiles of the gate of Kanazawa Castle and also in the covered gold plate found at Changuyong in Korea.

At the suggestion of Dr. R. Oppenheimer, a conference of chemists and archaeologists was held at the Institute of Advanced Studies, Princeton, in 1956, to examine the possibility of the use of nuclear analysis to help solve archaeological problems. Rising out of this meeting, work was undertaken in the United States at Brookhaven National Laboratory, and in Britain at the Research Laboratory for Archaeology and the History of Art of the University of Oxford. Sayre made the initial study of the method as applied to Mediterranean archaeology, and he irradiated sherds and fragments of figurines from Tarsus, Rhodes, Knidos, Boestia and Arezzo[11]. In an evaluation of this work it was decided that the results were encouraging, and that specific questions of archaeological analysis could be answered by activation analysis. This was followed[12] by a study of Mayan bowls and sherds from Piedras Negras and Kixpek in Guatemala, which were found to bear a strong chemical resemblance to each other. This type of pottery is found only rarely at Piedras Negras, but is extremely common at Kixpek. This analysis therefore lent strong support to the archaeological theory that the fine orange ware originated at Kixpek and was traded to Piedras Megras. In the same study, *terra sigillata* of the Roman period in Europe was analysed, and stamped Arretine sherds known to have been from bowls made at Arretium were compared with similar ware of uncertain origin found in other regions. Some pieces could be recognized by the analysis as having come from Arretium, while others which were suspected on typological grounds as being ancient forgeries (bearing the stamp 'ARRET' to obtain a higher market value) were found to differ in composition from the genuine Arretine pieces. Sayre has recently embarked[7,8] on a study of ancient glass; some work (as yet unpublished) has also been carried out at the Argonne National Laboratory on the analysis of both copper and obsidian. Most recently, there has been a programme of archaeological activation analysis undertaken by the Museum of Anthropology and the Chemistry Department at the University of Michigan, in Ann Arbor[13].

In Britain, the work on the archaeological use of neutron activation analysis has been as varied as in the United States, and not only has pottery been studied but also metals. The pottery studies are mainly the work of Emeleus, who pioneered the technique in Britain[14,15] and applied it particularly to Samian ware, *terra sigillata*[16–18]. Other workers concentrated on trace elements in coinage, especially gold and copper in early Greek silver coins[19–22]. More recently, the technique has detected silver in some late Roman coins[23] and has been used to analyse the famous Moulsford torc to show that it was of gold alloyed, either deliberately or naturally, with silver and copper[24].

In The Netherlands, an analysis has been made of electrum coins[25] and also a determination of the silver content of Greek coins[26]. This particular research has a novel feature in so far as a Van de Graaff generator was used as a source of neutrons for irradiation instead of a nuclear reactor.

We thank Dr. J. B. Griffin and Dr. A. Gordus for advice, during the course of our work while at the University of Michigan, and acknowledge the financial assistance given by the University of Michigan, Michigan Memorial Phoenix Project.

OBITUARIES

Prof. H. J. Bhabha

PROF. HOMI JEHANGIR BHABHA, chairman of the Indian Atomic Energy Commission, was killed with 116 others in an air-crash on Mont Blanc on January 24. He was on his way to Vienna to attend a meeting of the Scientific Advisory Committee of the International Atomic Energy Agency. He was a member of the Advisory Committee, and also of the Agency. Bhabha was a leader of science of the highest distinction, and his untimely death under poignant circumstances, at the height of his powers and influence, is a stunning blow to Indian science. It has left a void which will be difficult to fill. He was a theoretical physicist of world fame and one of the most gifted of scientific administrators to be found anywhere. The phenomenal progress made by India in atomic energy research and development will ever remain a lasting monument to Bhabha's vision, drive and dedication. He was a pioneer in several ways; and his great example will continue to be a source of inspiration for many years to come.

Homi Bhabha was born in Bombay on October 30, 1909, into a wealthy Parsee family related to the House of Tatas—he was a nephew of Lady Dorab Tata. He received his early education at the Cathedral and John Connon High School, Elphinstone College, and the Institute of Science, Bombay. After a brilliant academic record in India he joined Gonville and Caius College at Cambridge. He took the Mechanical Sciences Tripos in 1930. From 1932 until 1934 he held the Rouse Ball travelling studentship in mathematics, and worked with W. Pauli in Zurich and E. Fermi in Rome. He was awarded an Isaac Newton studentship in 1934, and a senior studentship of the Exhibition of 1851 in 1936. In 1940 he accepted a readership in theoretical physics, specially created for him, at the Indian Institute of Science, Bangalore. He was appointed professor in 1942. In 1945 he moved to Bombay to assume the directorship of the Tata Institute of Fundamental Research. The Institute, established at Bhabha's initiative, was made possible by a donation from the Sir Dorab Tata Trust. The Institute now has an academic staff of more than 200 and is almost entirely supported by the Atomic Energy Commission. It is interesting to recall that in 1944 Bhabha, in making his proposal to the Tata Trust, stated that his aim was "to build in the course of time a school of physics comparable to the best anywhere", and he continued, "when nuclear energy has been successfully applied for power production in say a couple of decades from now, India will not have to look abroad for its experts but will find them ready at hand". That all this has come about is a tribute as much to his vision as to his determination and single-mindedness in the pursuit of the goal that he had set for himself.

The Atomic Energy Act of India was passed in 1948. Under the Act the Atomic Energy Commission was set up with Bhabha as its chairman; he was also appointed secretary to the Department of Atomic Energy directly under the Prime Minister, in addition to the directorship of the Tata Institute of Fundamental Research and the Atomic Energy Research Establishment at Trombay. He enjoyed in full measure from the very beginning the support and confidence of the late Prime Minister Nehru, and this enabled Bhabha to lift the atomic energy programme to a level and carry it out with a speed which otherwise would scarcely have been possible.

The name of Bhabha will always remain associated with the beautiful theory (based on radiative energy loss by electrons, and pair-creation by photons), formulated jointly with W. Heitler in 1937, which has proved of fundamental importance in the understanding of the phenomenon of electron showers in cosmic rays. The theory was put forward simultaneously by J. F. Carlson and J. R. Oppenheimer. The mathematical aspects of the theory were developed further by Bhabha and S. K. Chakrabarty in 1943.

Bhabha was one of the earliest research workers to investigate the problem of scattering of mesons by nucleons and obtained (1938) an expression analogous to the Thomson scattering for light. He was the first to predict the lengthening with increasing energy, as required by relativity, of the decay-time of cosmic ray mesons.

Bhabha was elected a Fellow of the Royal Society of London in 1941. In 1943 he was awarded the Adams Prize by the University of Cambridge for his work on cosmic rays, and in 1948 the Hopkins Prize of the Cambridge Philosophical Society. In 1963 he was elected foreign associate of the U.S. National Academy of Sciences, and an honorary life member of the New York Academy of Sciences. In 1964 he was made foreign corresponding academician of the Royal Academy of Sciences, Madrid. From 1960 until 1963 he was president of the International Union of Pure and Applied Physics. Bhabha was president of the historic International Conference on the Peaceful Uses of Atomic Energy, held under the auspices of the United Nations, at Geneva in August 1955.

Bhabha was president of the National Institute of Sciences of India in 1963, and president of the Indian Science Congress Association in 1951. He was from the very beginning a member (and later chairman) of the

Scientific Advisory Committee to the Indian Cabinet—this Committee also acts as the National Committee for the International Council of Scientific Unions. He was a member of the Governing Body of the Indian Council of Scientific and Industrial Research, and of several committees concerned with planning and development of science. He was awarded the title of *Padma Bhushan* by the Indian Government in 1954. He received honorary doctorates from several universities in India and abroad, including London and Cambridge.

Bhabha's interests covered a wide range. He was fond of music, and was no mean musician and painter himself. He had a keen aesthetic sense and sophisticated tastes: the Tata Institute at Bombay is not only a great centre of vigorous research but it is also one of India's 'prestige buildings'.

He was a man of great personal charm. He was always eager to seek outstanding talent (even in fields remote from his own interests) and give it every possible encouragement. He had travelled extensively, and had wide international contacts. He will be sorely missed by his numerous friends in and outside India.

He is survived by his mother and a younger brother.

D. S. KOTHARI

Prof. T. J. Jenkin

PROF. THOMAS JAMES JENKIN, who died on November 7, 1965, was professor of agricultural botany at the University College of Wales, Aberystwyth, and director of the Welsh Plant Breeding Station from 1942 until he retired in 1950. He was an agricultural scientist of the highest repute, and his pioneer work on the breeding of improved varieties of grasses earned for him world-wide recognition.

As a young man, Jenkin could not have envisaged a scientific career, for this only became possible later by taking advantage of the few and unexpected opportunities that came his way.

Born in 1885 on a small isolated farm in North Pembrokeshire, his youthful ambition was to become a successful farmer, and for this purpose he attended, in 1907, a short course of one academic term in the University Department of Agriculture at Aberystwyth. However, in the following year he was seriously injured on the farm. This accident, which made him less fit for manual work, was probably the turning-point in his career, because it led him to further academic study. Following a continuation course of another term at Aberystwyth he was advised and encouraged to enter the Old College School at Carmarthen, where he achieved the distinction of obtaining university matriculation in one year. In 1910 he returned to Aberystwyth to read for a degree in rural science, where he graduated with first-class honours in botany in 1914.

After a year as agricultural organizer for the Counties of Brecon and Radnor, Jenkin was appointed adviser in agricultural botany at the University College of North Wales, Bangor, where he remained until his return to Aberystwyth to occupy a similar post in 1919. This gave him the opportunity to study the botanical composition and productivity of sown pastures, when he showed that the varieties of herbage plants then available lacked persistency in the sward and were soon replaced by indigenous grasses. His work attracted the attention of Prof. (later Sir) R. G. Stapledon, and he joined the newly established Welsh Plant Breeding Station as senior research assistant in 1920. This was the beginning of a long and fruitful association between two great agricultural scientists who, although differing widely in personality and in their scientific approach and methods, made outstanding contributions to grassland improvement and productivity.

Jenkin's extensive collection of indigenous grasses, which showed considerable genetic variation, formed the basis for the deliberate breeding of improved varieties. The techniques for controlled hybridization had to be developed, but even after adequate testing of the progeny as single plants he was confronted with the problem of assessing the value of a combination of favourable genotypes when grown in a sward under highly competitive conditions. Without modern knowledge of population genetics he was extremely successful in producing a series of improved varieties which maintained their identity and performance after several generations of seed production. His variety *S*23 of perennial ryegrass has probably contributed more to the improvement of both hill and lowland pastures in Britain than a whole series of commercial seed mixtures.

Although the greater part of his work involved the production of new varieties for use on the farm, Prof. Jenkin was able to conduct pioneer research on interspecific and inter-generic relationships of the grasses, particularly *Lolium*, *Festuca* and *Phalaris*. He was awarded the degree of D.Sc. for these investigations.

As professor and director he guided the work of the Department of Agricultural Botany and the Welsh Plant Breeding Station with distinction throughout the difficult war and immediate post-war years, and when he retired in 1950 he was made a C.B.E. He was later awarded the Gold Medal of the Royal Welsh Agricultural Society and made an Honorary Member of the Swedish Seed Association for his outstanding contribution to agriculture.

Thomas James Jenkin belonged to that unique band of pioneers who have contributed so much towards the advancement of agriculture, and future generations will acknowledge their debt to the young Pembrokeshire farmer who became an outstanding agricultural scientist.

P. T. THOMAS

Prof. Ferdinand Herčík

PROF. F. HERČÍK died on January 20 at the age of sixty. He was director of the Institute of Biophysics of the Czechoslovak Academy of Sciences at Brno since its inception in 1955. One of the foremost contemporary research workers of Czechoslovakia, his work was widely known throughout the world and his friendship was cherished by many of us who had the good fortune to know him well. His activities in connexion with the affairs of the United Nations Organization brought him into extensive touch with Western scientists. Being a member of the United Nations Scientific Committee on the Effects of Atomic Radiation and a governor and vice-chairman of the International Atomic Energy Agency made it possible for him to travel and to meet colleagues freely at a time when contacts between Eastern and Western scientists were much more restricted than they are now. When chairman of the United Nations Scientific Committee, his tact, perseverance and unquestionable integrity made it possible for this Committee to publish a balanced and unanimous report, though there was then no test-ban treaty and the question of the hazard from fall-out was in the arena of emotion and politics. At the International Atomic Energy Agency, Prof. Herčík was tireless in his support for fundamental investigations on the biological effects of radiation, which he considered an essential part of any research programme designed to further the peaceful uses of atomic energy. His unique status enabled him to ensure that investigations into the problems of health and safety were not too narrowly based and he emphasized the importance of studying chemical agents which modified the degree of biological damage produced by a given dose of radiation.

These achievements as a scientific statesman required more than technical competence, and as soon as one met him one was struck by his extremely rich personality. He was a talented and very active painter, had a passion

for mountaineering and a full and very happy family life. An abiding impression of a visit to his Institute was the intense affection and admiration in which he was held by members of his staff. He defended and protected their scientific integrity under conditions which were not always easy and his reward was that the Institute he established had in the surprisingly short time of ten years acquired a world reputation. The work of the Institute is of a very high quality and shows a marked originality of approach which may, in part, be the outcome of struggling with shortages and difficulties in obtaining the most modern equipment.

Prof. Herčík's own researches were varied; being trained both in medicine and in physics, he held at different times chairs in both schools of medicine and of science. After his thesis, taken in Brno, which dealt with surface tension in relation to biology, he worked for a time at both the Pasteur Institute in Paris under Lecomte du Nouy and in the Rockefeller Institute in New York under R. W. G. Wyckoff. He was among the first to appreciate the importance of electron microscopy in biology and medicine, but he is perhaps best remembered for his researches into radiation effects at the cellular and sub-cellular level, where he made full use of viruses and micro-organisms to elucidate basic mechanism. He brought to biophysics the extensive knowledge and breadth of interest which a successful pursuit of this complex subject demands. PETER ALEXANDER

NEWS AND VIEWS

New Fellows of the Royal Society

AT a meeting of the Royal Society on March 17, the following were elected to fellowship of the society: PROF. A. R. BATTERSBY, professor of organic chemistry in the University of Liverpool; DR. T. BROOKE BENJAMIN, assistant director of research, Department of Engineering and Department of Applied Mathematics and Theoretical Physics in the University of Cambridge; DR. K. G. BUDDEN, lecturer in physics at the Cavendish Laboratory, in the University of Cambridge; PROF. R. E. DAVIES, professor of biochemistry and chairman, Department of Animal Biology in the University of Pennsylvania, School of Veterinary Medicine, Philadelphia; DR. W. R. S. DOLL, director of the Medical Research Council Statistical Research Unit and lecturer in Medical Statistics and epidemiology at University College Hospital Medical School in the University of London; PROF. S. F. EDWARDS, professor of theoretical physics in the University of Manchester; DR. J. S. Forrest, director of the Central Electricity Research Laboratories, Leatherhead, Surrey; DR. F. C. FRASER, keeper of zoology and deputy chief scientific officer at the British Museum (Natural History), London; PROF. H. HARRIS, Galton professor of human genetics, head of Department, and director of the Galton Laboratory at University College, in the University of London; PROF. D. O. HEBB, professor of experimental psychology in McGill University, Montreal; SIR WILLIAM HUTCHISON, deputy chairman, Gas Council, London; DR. A. ISAACS, member of scientific staff, National Institute for Medical Research, London; DR. B. KASSANIS, senior principal scientific officer at the Department of Plant Pathology, Rothamsted Experimental Station, Harpenden, Herts; DR. R. A. KEKWICK, reader in chemical biophysics and head of the Department at the Lister Institute of Preventive Medicine, in the University of London; DR. P. E. KENT, chief geologist, British Petroleum Co. Ltd., London; MR. D. G. KING-HELE, senior principal scientific officer, Royal Aircraft Establishment, Farnborough, Hants; SIR FRANCIS KNOWLES, reader in comparative endocrinology at the Medical School, University of Birmingham; PROF. G. KREISEL, professor of mathematics in the University of Paris; DR. C. E. LUCAS, director of Fisheries Research for Scotland (Department of Agriculture and Fisheries for Scotland) and director of the Marine Laboratory, Aberdeen; PROF. J. D. MCGEE, professor of applied physics, at the Imperial College of Science and Technology, in the University of London; DR. J. W. MENTER, director of research and development, Tube Investments, Ltd., Hinxton, Cambridge; DR. A. E. MOURANT, director, Medical Research Council Serological Population Genetics Unit, at St. Bartholomew's Hospital, London; PROF. E. S. PEARSON, emeritus professor of statistics at University College, in the University of London; PROF. D. H. PERKINS, professor of elementary particle physics at the Nuclear Physics Laboratory in the University of Oxford; DR. LILLIAN M. PICKFORD, reader in physiology in the University of Edinburgh; PROF. H. O. SCHILD, professor of pharmacology at University College in the University of London; DR. H. M. STANLEY, director and controller of Research and Development Division, The Distillers Co. Ltd., London; PROF. B. A. D. STOCKER, professor of medical microbiology in Stanford University, California; PROF. J. SUTTON, professor of geology and head of the department at the Imperial College of Science and Technology, in the University of London; PROF. M. SZWARC, research professor and director of polymer research at the State University College of Forestry, in Syracuse University, N.Y.; DR. D. H. WHIFFEN, deputy chief scientific officer, Basic Physics Division at the National Physical Laboratory, Teddington, Middlesex; SIR FREDERICK WHITE, chairman of the Commonwealth Scientific and Industrial Research Organisation, Canberra.

Structural Chemistry in the Bradford Institute of Technology : Prof. D. A. Long

Dr. D. A. LONG, who has been appointed to the new chair of structural chemistry in the Bradford Institute of Technology (proposed University of Bradford), was educated at Sir Thomas Rich's School, Gloucester, and Jesus College, Oxford, where he graduated in 1947 with first-class honours. Dr. Long then carried out postgraduate research with Dr. L. A. Woodward and Mr. R. P. Bell. After completing the degree of D.Phil. in 1949, he spent a year with Prof. B. L. Crawford in the University of Minnesota and then returned to Oxford as Pressed Steel Research Fellow in spectroscopy from 1950 until 1955. During this period he continued his studies in spectroscopy, concentrating particularly on intensities of vibrational Raman spectra. He was appointed lecturer in chemistry at the University College of Swansea in 1956 and was promoted to senior lecturer in 1958 and to reader in 1963. During his period in Swansea, Dr. Long continued work on Raman intensities and in the application of computer techniques to the study of force constants. More recently he has investigated the use of lasers in both Raman and the stimulated Raman effect. He has also undertaken studies of the kinetics of hydrolysis of peptides. In 1964 Dr. Long was awarded an Organization for Economic Co-operation and Development senior visiting fellowship of the Department of Scientific and Industrial Research, to enable him to visit a number of centres of laser research in the United States and Canada.

Port Development

IN replying for the Government in a short debate on port development in the House of Commons on March 9, the Joint Parliamentary Secretary to the Ministry of

Transport, Mr. S. Swingler, said that planned capital investment in the ports in 1965–66 was £29·9 million compared with £18 million in 1964–65, and under the National Plan would rise to £51 million in 1966–67 and to £63 million in 1967–68. Work on the Tilbury development scheme of the Port of London Authority had been put in hand to the extent of £10 million. Improvements to the Royal Edward Dock at Avonmouth had been authorized to the extent of £750,000. Work was about to start on the new lock at Grangemouth under a £7 million scheme. Work was also in hand at Leith which represented an investment of £6 million. The Portbury scheme put forward by the Port of Bristol Authority was an imaginative scheme of great merit and was being very carefully considered, but Mr. Swingler was not able to announce a decision.

Finance for Research and Development

IN written answers in the House of Commons on March 9, the Minister of State, Department of Education and Science, Mr. R. E. Prentice, stated in 1964–65 research and development in the United Kingdom financed from Government sources was provisionally estimated at £427 million. Of this, £177 million was in Government research establishments, £49 million in universities and technical colleges; and £187 million in industry; for 1955–56, the corresponding figures were £222·2 million; £78·3 million; £11·8 million; and £128·4 million, respectively; in 1958–59, £316·1 million; £134·9 million; £18·7 million; and £155·9 million; and in 1961–62, £385 million; £163·1 million; £27·6 million; and £180·5 million, respectively. It was estimated that in 1964 about 7,000 scientists and engineers emigrated from Britain and there were about 4,500 immigrants.

British Research and Development Reports

THE first number, for January 1966, of the bulletin, *British Research and Development Reports*, issued by the National Lending Library for Science and Technology, opens a series intended both to direct attention to the existence of such reports and to increase their flow. The reports are treated as part of the collection of the Library and will be available through its normal services. They include reports from defence or industrial organizations which have no security or commercial limitations on availability and reports from university laboratories containing so much numerical data that they are too large for normal publication. The subjects covered include science, technology (including agriculture and medicine) and the social sciences. The subject headings used are deliberately broad and in the first issue entries are predominantly under engineering.

The National Plan

"THE National Plan—Its Contribution to Growth" is the title of a broadsheet by Geoffrey Denton (*Planning*, 31, No. 493, 331. London: Political and Economic Planning, 1965. 6*s*.). Mr. Denton examines the nature of the Plan adopted by the past Government and tries to suggest how planning might be developed to the advantage of the British economy. Mr. Denton deals first with the Plan as a forecast and then as a target and a feasibility study. He goes on to consider the Plan as a directive and deals finally with the value of such a plan and with the type of plan which is desirable. Mr. Denton thinks that the Plan cannot be regarded as an alternative to the major political changes which may be required, and he feels that the need to ensure appropriate democratic control over the planning process is a further argument for considering the implications of alternative rates of growth. The method by which an indicative target plan of this type can promote faster growth has not adequately been explained, and it may well be an uncertain basis for this operation. While showing awareness of the relation between targets and the policy measures necessary to fulfil them, the Plan fails to indicate convincingly how the present balance of payment figures can be integrated with policy in a manner which can fill the gap between forecast and plan. National plans can nevertheless contribute much to the successful management of the economy. The broadsheet indicates one way in which the Plan could possibly be adapted to provide a faster rate of economic growth.

University News: School of Pharmacy

THE Council of the School of Pharmacy, University of London, has conferred Honorary Fellowship of the School on Sir Harry Jephcott, in recognition of his great services to the School over many years. Sir Harry Jephcott has been chairman of the School Council since its formation in 1948.

Manchester

DR. F. R. JEVONS, at present lecturer in biological chemistry, has been appointed to a newly established chair of liberal studies in science.

Strathclyde

D. S. BUTLER, reader in numerical analysis in the Department of Mathematics at the University of Strathclyde, has been appointed professor of numerical analysis as from April 1.

Sussex

PROF. G. A. SIM, at present professor of physical chemistry in the University of Illinois, has been appointed professor of chemistry.

Appointments

DR. J. L. GODDARD is to be commissioner of the Food and Drug Administration of the U.S. Department of Health, Education and Welfare. He was previously chief of the Communicable Disease Center, Public Health Service.

G. R. W. DE SILVA has been appointed director of the Division of Conference and General Services of the International Atomic Energy Agency in succession to D. G. Sullivan.

H. E. RILEY, formerly chief statistician at the International Labour Office, has been appointed head of the Office of Economic and Manpower Studies of the U.S. National Science Foundation.

Announcements

THE spring meeting of the British Biophysical Society, on "Excitable Tissues", will be held in the University of Oxford during April 14–15. Further information can be obtained from Dr. A. R. Peacocke, St. Peter's College, Oxford.

A SYMPOSIUM on "Aspects of Surface and Colloid Chemistry" will be held at the John Dalton College of Technology on April 15. Further information can be obtained from Dr. A. Powell, Department of Chemistry, John Dalton College of Technology, Chester Street, Manchester 1.

A MEETING of the Thermal Analysis Group of the Society for Analytical Chemistry will be held at the Royal College of Advanced Technology, Salford, during April 21–22. Further information can be obtained from the Society for Analytical Chemistry, 14 Belgrave Square, London, S.W.1.

A CONFERENCE on "Phonons", arranged by the Institute of Physics and the Physical Society, will be held in the University of Edinburgh during April 6–7. Further information can be obtained from the Meetings Officer, the Institute of Physics and the Physical Society, 47 Belgrave Square, London, S.W.1.

CHEMICAL CARCINOGENESIS

A SERIES of six lectures entitled "Chemical Carcinogenesis" was given at the Northern Polytechnic, London, between October 7 and November 14, 1965. Their purpose was to publicize the carcinogenic hazards of chemicals, particularly to those engaged in the production and marketing of chemical, rubber and pharmaceutical products. The course was inspired by an article by Prof. A. Haddow (*New Scientist*, 25, 348; 1965) entitled "Control of Cancer-inducing Chemicals", and Prof. Haddow very kindly helped to plan the course in its initial stages. The need for these lectures was shown by the high level of attendance at the meetings, and by letters from people expressing regret at not being able to attend and asking for abstracts. The lecturers, who kindly supplied abstracts for inclusion in this report, were: Prof. A. Haddow, director of the Chester Beatty Research Institute, London; Prof. E. Boyland and Dr. F. J. C. Roe (Chester Beatty Research Institute); Dr. P. N. Magee (Toxicology Research Unit Medical Research Council Laboratories, Carshalton, Surrey); and Miss Joan Davies (The Royal Marsden Hospital, London).

The meetings began with a lecture by Dr. P. N. Magee on carcinogenesis by nitroso compounds.

A large number of *N*-nitroso compounds are known to be capable of inducing cancer in experimental animals[1–5]. These compounds are among the most potent of all known carcinogenic substances[6,7]. The simplest member of the dialkylnitrosamine series, dimethylnitrosamine, is a powerful liver poison, causing necrosis of the liver in all the common species of laboratory animal[8]. When continuously fed to rats, mice and hamsters it induces malignant tumours of the liver in high incidence[1]. When given to young adult rats for shorter periods at higher levels, and even in survivors of single large doses, kidney tumours are induced but no liver tumours[2]. Injection into newborn rats is followed after about a year by kidney and liver tumours[9]. Dimethylnitrosamine is rapidly metabolized[10] and a large part of the carbon of the injected dose is excreted in the expired carbon dioxide[11,12]. The liver appears to be the main organ concerned with metabolism which is enzymatically mediated[13,14]. The kidney and probably some other organs in the rat are also capable of metabolism of dimethylnitrosamine but much less actively than the liver. One metabolic pathway appears to involve oxidative removal of a methyl group with the formation of the very unstable monomethylnitrosamine which decomposes spontaneously to yield an active alkylating intermediate, possibly the corresponding diazoalkane[15,16]. There are certainly other metabolic pathways of dimethylnitrosamine but these have been less thoroughly investigated.

A hypothesis to explain the toxic, mutagenic and carcinogenic action of the nitroso carcinogens suggests that the active agent concerned is the alkylating intermediate. Evidence in support of this hypothesis comes from examinations of carcinogenic activity in relation to chemical structure with a large number of nitrosamines[4], although certain discrepant features remain unexplained. Direct evidence of alkylation of tissue constituents has been obtained with the demonstration that proteins and nucleic acids become alkylated in animals injected with dimethyl and other nitrosamines[15,16]. Alkylation, mainly on the 7-position of guanine, occurs in the DNA and RNA of liver and kidney in the treated animals[16]. The methyl group in both the methylated DNA and RNA is unstable and rapidly disappears from the nucleic acids *in vivo* at a rate which cannot be explained by normal metabolic turnover[17]. This alkylation reaction is the same, chemically, as that which is suggested to underlie the mutagenic action of the biological alkylating agents. Whether it underlies the carcinogenic action of the nitroso carcinogens remains to be established.

Prof. E. Boyland devoted two lectures to discussing the biochemistry of a wide range of chemical compounds.

As most cancer is caused by chemical substances in the environment, study of the biochemistry of chemical carcinogens is of interest because it should lead to the prevention of the disease. Some carcinogenic compounds act without previous metabolic change and are considered to be direct carcinogens. Alkylating agents, which include mustard gas, nitrogen mustards, methylsulphonyl esters, lactones and epoxides, are probably direct carcinogens of this type. They react with the purine, guanine residues of nucleic acid. The nucleic acid is thus changed so that mutations and cancer result.

On the other hand, the aromatic amines, 2-naphthylamine, benzidine, and 4-aminobiphenyl, which induce cancer of the bladder, are carcinogenic after metabolic activation and are therefore indirect carcinogens. The active metabolites are derivatives of arylhydroxyamines and *ortho* aminophenols which can induce cancer of the bladder directly.

Most chemical carcinogens have been first recognized through accidental industrial exposure. An early example of this was the recognition of scrotal cancer in chimney sweeps as a consequence of exposure to the soot of chimneys (Percival Potts, 1775). The observation that soot and coal tar were carcinogenic led to the isolation of the active polycyclic hydrocarbon, 3,4-benzpyrene. Following this, a number of related polycyclic hydrocarbons were synthesized and tested by Cook and Kennaway, and the relationship of chemical structure and biological activity investigated. It is not known whether these hydrocarbons require metabolic change before exerting their biological action.

Urethane, which was used as an anaesthetic, as a solvent for drugs and in the treatment of leukaemia and myeloma, is also carcinogenic. Urethane is converted by mammals to *N*-hydroxyurethane, which has many biological activities that urethane does not possess. *N*-hydroxyurethane and some related hydroxylamine derivatives are carcinogenic and also inactivate the Shope fibroma virus and other viruses *in vitro*. The mechanism of action of *N*-hydroxyurethane and its analogues is probably due to reaction with the pyrimidine base, cytosine, of nucleic acids.

Many of the compounds used in the chemotherapy of cancer (such as nitrogen mustards, urethane and oestrogens) are carcinogenic. Knowledge of the mode of action of these substances is therefore of value both in prevention and treatment of cancer.

Prof. A. Haddow spoke on the heterogeneity of carcinogens and questions of the mechanism of action. An outstanding feature in carcinogenesis was the great number and variety of causative agents, whether chemical, physical or viral. This made it certain that such agents operate by biochemical routes which, initially at least, must be correspondingly different. However, it could by no means be excluded that they could lead to a key cellular event or alteration, similar, or perhaps even identical, in the different cases. Hence there was a prospect of the emergence, from a picture of great complexity, of a more synthetic comprehension of the carcinogenic process, with all that this could mean towards elucidating the essential biochemical differences between normal and cancer cells, and perhaps in turn, to rational

methods of control and even prevention. Prof. Haddow illustrated this theme by accounts of the carcinogenic hydrocarbons, aminostilbenes, aromatic amines, the biological alkylating agents, metals and metal–carbohydrate complexes, and of such miscellaneous examples as asbestos, the cycads, and the recently discovered aflatoxins. It was remarkable that, even now, so little was known with any precision as to the mode of action of the carcinogenic hydrocarbons. Their molecular planarity had suggested a possible interaction with the nucleotide plates, but this view might require to be modified or abandoned in view of the more recently recognized non-planarity of the potent 9 : 10-dimethyl-1 : 2-benzanthracene. However, other collateral evidence (for example, solubilization of the polycyclic hydrocarbons by purines and nucleic acids) still suggested some type of interaction with DNA, and a special case being widely investigated was that of the possible intercalation of hydrocarbon molecules between adjacent base-pair plates.

Of all the classes of chemical carcinogen, it was perhaps in the field of the alkylating agents (such as nitrogen and sulphur mustards, *bis*-epoxides, polyethyleneimines, dimesyl compounds, lactones and alkylnitrosamines) that most progress had been made in the past 15 years—largely as a result of the relative simplicity and higher chemical reactivity of these agents. Most remarkable was the demonstration by Brookes and Lawley of alkylation in guanylic acid at position 7, and of *bis*-guanyl and similar products almost certainly derived from inter-chain cross-linking of the DNA helix. That many of the DNA-viruses might act by modification of the genome similar to the cytogenetical changes induced by chemical agents was one of the considerations prompting hopes of an eventual synthetic understanding.

Miss Joan Davies spoke about occupational bladder tumours. More than 2,000 men die with bladder tumours every year in England and Wales, and some of these tumours are of occupational origin. If a bladder tumour is diagnosed at an early stage, treatment may be simple and effective, but often a tumour does not cause any symptoms until it is comparatively advanced, and treatment is then more difficult. This is why early diagnosis by means of cytological screening (regular microscopic examination of urine samples) is important for groups of workers who run an enhanced risk of developing the disease—groups such as certain chemical workers for whom the Association of British Chemical Manufacturers set up a screening service in 1956.

In 1954 a high risk of bladder tumours among men working in firms manufacturing alpha-naphthylamine, beta-naphthylamine and benzidine had been demonstrated[18]. Between 1921 and 1952, 243 out of 2,500 workers had developed the disease and half these had died as a result (at an average age of about 55). Another 250 would probably develop tumours in due course, for some 18 years usually elapsed between starting work with the chemicals and the onset of the disease. Beta-naphthylamine was the most dangerous chemical. The longer a man worked with these substances, the more likely he was to be affected, but even brief and indirect contact could cause tumours.

Until 1949 the rubber industry made extensive use of antioxidants containing alpha- and beta-naphthylamine, and in 1954 Case and Hosker[19] directed attention to an excess risk of death from bladder tumours among skilled rubber workers. However, no full survey has ever been made to determine the size of the risk or the range of workers affected. In 1956–57 the Rubber Manufacturing Employers' Association set up a screening service, but by no means all member firms made use of this service and many exposed rubber workers were not screened until very recently.

The same anti-oxidants were used until 1949 in insulating rubber in the electric cable industry, but here the risk apparently went unheeded until recent publicity following the inquest on a former cable worker[20]. The severity of the risk can be gauged by the finding[24] that in the rubber mill of one cable factory thirty out of 139 men had worked for 10 or more years in contact with such an anti-oxidant, and six of the thirty have so far developed bladder tumours (four of these dying of the disease). Apparently no cable workers were screened until after the inquest mentioned. As well as definitively identifying the carcinogens responsible, a full survey of the rubber and cable industries might identify the workers running the greatest risk of developing the disease, and so enable screening priorities to be established.

In 1953, bladder tumour was made a prescribed industrial disease under the Industrial Injuries Acts, but through a general lack of awareness many rubber and cable workers with the disease (or their widows) have never been advised to claim the extra financial benefits to which they are entitled.

The final lecture was given by Dr. F. J. C. Roe, who reviewed the evidence that some metals, minerals and pharmaceutical preparations are capable, under certain conditions, of inducing cancer in laboratory animals or man. Among the metals, clear evidence of tumour induction has been obtained in the cases of arsenic, beryllium, cadmium, chromium, cobalt, lead, nickel and zinc. Arsenic is undoubtedly carcinogenic for man but it has not been shown to be so for other species. Some of the other metals, such as lead and zinc, have not yet been shown to be carcinogenic in man. Asbestos has recently been found to be the principal cause of a rare type of human tumour, the mesothelioma. Also, it is now clear that the association between lung cancer and asbestosis is both definite and strong.

A wide variety of pharmaceutical preparations have been shown to be carcinogenic in laboratory animals. A few have been shown to induce cancer in man. Where the use of such preparations is life-saving, it may be necessary to accept a risk that cancer will be induced in a proportion of patients. But where non-carcinogenic alternatives exist, or where the benefits to be expected from the use of a drug are small, the continued prescribing of carcinogenic agents cannot be justified. A full report of the preparations considered is due to appear shortly elsewhere[22].

Of special importance in relation to the carcinogenic hazard from drugs is the difficulty of extrapolation from animal experiments to man. Whereas potent carcinogens are frequently active in almost all species, weaker agents may not be so. Thus, a weak effect observed in one animal species may be unmatched by a similar response in another. It is important, therefore, to have information on tests in more than one species. An experiment on animals is more likely to be relevant to the human situation if the dosage used is realistic and the route and mode of administration the same, or comparable. One of the most contentious problems is knowing how to interpret the induction of cancers in animals by the parenteral administration of a substance normally given orally to man. In general, the need for greatest concern relates to drugs which, if they are taken at all, tend to be taken in large doses over long periods, and to drugs freely available without medical prescription. The real risk of cancer induction in man by such substances should be ascertained by epidemiological methods, though this may be impossible where a drug can be bought without prescription. Epidemiological surveys are expensive and often slow to yield results. If a new drug were introduced to-day, it may be more than 20 years before its carcinogenic action in man could be detected by epidemiological means, because of the long latent periods generally required for the induction of human cancer. In the meantime, the best use must be made of experimental findings to guide prescribing practice.

The importance of the subject was underlined by Dr. Roe, who suggested that as much as 75 per cent of human

cancer is attributable to exposure to carcinogenic agents in the environment and therefore potentially preventable. Potent carcinogens tend to reveal their activity sooner or later, even if no careful investigation is made. The real difficulty relates to weaker agents, none of which by themselves has a marked effect on cancer incidence, but which, together, may very materially increase the cancer burden.

RECENT ADVANCES IN THE MICRO-IRRADIATION OF CELLS

RESEARCH workers who are interested in the effects of microbeams of radiation of a variety of biological materials met recently to discuss problems which are currently important in the development of this subject. The meeting was arranged by Dr. M. Bessis and was held in the Laboratoire de Pathologie Cellulaire, le Kremlin-Bicêtre, Paris.

Dr. C. L. Smith (Cambridge) was chairman for the first session, which was concerned with recent advances in the design and construction of microbeams and opened with some comments by H. Glubrecht (Hannover) on the development of an ultra-violet microbeam coupled with an ultra-violet microspectrophotometer of the Caspersson type. He emphasized that the dose of ultra-violet radiation which was used for microspectrophotometric measurements on living cells should be not more than one-thousandth of that which had been used in the microbeam to irradiate the cells. In answer to L. Trapp (Zeiss, Oberkochen) he said that ultra-violet absorption measurements had been made over areas varying from 0·7μ to 12μ and dose-rates had been obtained by taking into consideration the reflexion and transmission coefficients of all the relevant surfaces. G. Nomarski (Paris) indicated the importance of increasing the ultra-violet reflecting power of aluminized mirrors above the normal figure of 85 per cent, particularly in arrangements where there could be as many as ten to sixteen reflexions.

Nomarski then gave details of developments in laser techniques. It is now possible to produce a beam which is constant in intensity over an area approximately equal to that of a single cell, and dose reproducibility has been improved to about 10 per cent by surrounding the laser with a 0·5-mm thick water jacket. The available wavelengths may soon be extended by harmonic generation from two fundamental wave-lengths at 6940 Å and 10600 Å with the aid of a new crystal and, in the near future, repeatable pulses varying in length from 50 μsec to 6 msec at 0·1-sec intervals may be available. Glubrecht suggested that when this became possible dose-rate effects would be very interesting, and drew an analogy with pulse radiolysis.

There was then a discussion on the importance of localization of the radiation delivered by a microbeam system, and Nomarski indicated that, for ultra-violet light, precision of the order of 0·15μ was possible for a thin target. P. P. Dendy (Cambridge) and A. Forer (Copenhagen) both supported the importance of precise physical location but drew attention to biological difficulties which include the unavoidable irradiation of membranes and other cell parts in addition to the target, and the ease with which biochemical changes can be transferred from the site of the primary lesion.

M. Ernst (Hannover) described a recently constructed X-ray microbeam which uses 5-keV X-rays to irradiate an area approximately 4·5μ in diameter. The whole apparatus is contained in a constant-temperature box which can be sterilized. In this way, uncovered biological specimens can be used, and this, in turn, allows the use of lower-voltage X-rays which give a better localization of energy. The apparatus was compared with the earlier models of Seidel and Buchholtz[1] and Seed[2].

A discussion on the production of small holes followed and Nomarski indicated that 1μ-diameter holes in 10μ-thick tungsten could be produced by laser radiation. H. Mel (Paris) told the meeting about a relatively new procedure in which small areas of a surface can be weakened by the deposition of certain elements followed by neutron irradiation. Suitable chemical treatment leads to the production of very small regularly shaped holes at the weakened sites.

Smith gave a brief outline of a new electron microbeam which is being built in Cambridge. It is hoped ultimately to obtain a 3μ spot of 50-keV electrons, and incident illumination coupled with phase contrast will be used to view the biological material and control the site of irradiation.

The session ended with a description by Forer of a modified reflecting objective which permits the observation of a cell in polarized light under phase contrast conditions during ultra-violet microbeam irradiation. Nomarski pointed out the advantage of circularly polarized light for this type of work, particularly at high numerical apertures.

In the second session, the results of some recent experiments were presented. Prof. H. Glubrecht (Hannover) took the chair and suggested that the speakers should try to show how their experiments had extended ancillary techniques and quantitative methods for assaying the biological effect, both of which are strictly limited in microbeam work. Bessis described some work in which mitochondria in *KB* cells had been stained with various vital stains. At staining concentrations which were twenty times lower than the limit of visibility, mitochondria became highly sensitive to laser microbeam irradiations. An electron microscope study of the irradiated cell showed that mitochondria which had been hit were extensively damaged. Certain mitochondria which were not in the irradiated region showed structural changes 2–3 h after irradiation but they had recovered by 24 h.

A discussion followed on valid criteria for deciding if a cell is alive, and Bessis stated that, in their work, the ability to take up nucleic acid precursors and the activity of enzymes had been used as criteria. This point was taken up by the next speaker when Dendy discussed some experiments which had been performed at Cambridge. He referred briefly to earlier micro-irradiation

experiments in which effects had only been investigated for a few hours and it had been realized that an important factor in the cell viability problem was the ability or otherwise of irradiated cells to develop into colonies. The most recent experiments had therefore been designed to study the development of single cells for 7 days after irradiation with a microbeam of heterochromatic ultra-violet light. At the end of this time, several irradiated cells had formed small colonies which contained a number of morphologically normal cells. A study of the DNA metabolism of individual cells in these colonies at 7 days showed many anomalies, even in the morphologically normal cells.

Forer gave a brief account of the use of polarizing microscopy coupled with ultra-violet microbeam irradiation to study the effects on chromosome separation when a small volume of the spindle fibres is irradiated, and Glubrecht presented some results which were obtained when moss cells were irradiated with a monochromatic ultra-violet microbeam. In the latter experiments, cell killing was most efficient when radiation at $\lambda = 2650$ Å was directed at the nucleus but $\lambda = 2800$ Å was most efficient when directed at the cytoplasm.

The meeting ended with a tour of the new Laboratoire de Pathologie Cellulaire, and the Chairman thanked Prof. Bessis for making all the arrangements for the meeting and thanked the representative of NATO, Ing. Gen. Giboin, for financial support. P. P. DENDY

IODINE-LABELLED PROTEINS AND HORMONES

ENCOURAGED by the success of a symposium in 1964 on the preparation and biomedical application of labelled molecules Euratom has sponsored another more specialized meeting on problems connected with the preparation and use of labelled proteins. This was held at the University of Pisa in January 1966 and attracted some 150 participants. As might be anticipated from a survey of the literature, nearly all the communications were concerned with proteins labelled with iodine isotopes, the 3-day conference being broadly equally divided into sessions on hormones and non-hormonal plasma proteins.

Hughes (Boston) reviewed the chemistry of iodination and the particular chemical requirements for satisfactory trace-labelling of proteins. For most purposes the protein should retain its biological activity after labelling. He considered that iodotyrosines might conceivably be used *in vivo* for protein synthesis but the opportunity seldom presented for this to happen because of the widespread distribution and rapidity of action of tissue deiodinases. Rosa (Saluggia) emphasized the importance of achieving a truly random distribution of isotopic iodine throughout the population of protein molecules and produced further details of the electrolytic method of doing this which he has elaborated in collaboration with Donato and his group at Pisa. It remained for Freeman (London) to discuss biological methods of verifying that the labelled protein is a reliable tracer since it is generally accepted that only *in vivo* tests are sufficiently sensitive. He mainly favoured measurements of retention in the livers of rats, of catabolic rates in rabbits (if necessary rendered tolerant to human proteins), and of iodide activities in the urine and body water in the first 24 h in man. These and other speakers emphasized the crucial importance of using only proteins which have been circumspectly handled before labelling, and of taking steps afterwards to minimize self-irradiation damage.

In introducing a session on metabolic studies with labelled plasma proteins McFarlane (London) recommended that speakers should refer specifically to absolute or fractional rates of turnover as the case might be. Since iodine isotopes are not used for protein synthesis, conclusions about synthesis can only be derived indirectly from slopes of plasma specific activity curves of animals in metabolic equilibrium. These are proportional to fractions of the total body pool synthesized in unit time whereas currently used procedures for measuring catabolic rates give them as fractions of the plasma pool. It was important therefore also to specify the pool. Bianchi (Pisa) and Sorin reviewed the use of iodine-labelled albumin in metabolic studies, Andersen (Copenhagen) did the same for γ-globulin and Regoeczi (London) for fibrinogen. These were mainly straightforward communications, but controversial questions arose when subsequent speakers discussed mechanisms for regulating plasma protein turnover. Rothschild (New York) reported results of experiments in which low albumin concentrations were produced in rabbits by infusing γ-globulin or dextran and in which little or no change was observed in the mass of albumin catabolized per day. Fractional synthesis rates in these experiments were unrelated to fractional or absolute catabolic rates, to albumin pool sizes or to concentrations and in fact were sub-normal. This apparent paradox could be resolved by postulating a control mechanism based on the colloid osmotic pressure of hepatic interstitial albumin which is assumed to be increased by injections of γ-globulin or dextran. Dykes (Birmingham), on the other hand, found greatly reduced absolute catabolic rates in cirrhotic patients with low albumin concentrations both of which were restored to normal by infusions of albumin. He visualized a second-order relationship between albumin concentration and absolute catabolic rate.

Included in a variety of shorter papers were descriptions of the preparation and use of tritium-labelled plasma proteins by Gostonyi *et al.* (Budapest) and by Gerber *et al.* (Mol, Belgium). Gordon and Jacques (London) reported on the distribution of iodine-labelled proteins in subcellular particles of the rat liver. Høedt-Rasmussen (Copenhagen) reported on a 10–20 per cent extravascular catabolism of parenterally administered albumin, and Milhaud (Paris) on the effects of ligaturing the thoracic duct on ^{131}I-albumin distribution and metabolism in rats.

Most fittingly, a culminating session to this part of the conference consisted of a round-table discussion of mathematical methods of analysing results. Experts on the panel comprised Donato (Pisa), Matthews (London), Nosslin (Malmö), Segrè (Camerino), and Vitek (Prague). The more recently published methods of Nosslin, which are largely independent of compartmental considerations, received most attention. While Nosslin agreed that his second method, which is based on integrating areas under plasma and total body activity curves, might be less vulnerable to errors associated with identifying terminal slopes of these curves, he considered it was not altogether free of them, and indeed that the accuracy of all methods was to some extent limited by this factor. The deconvolution method of Vitek and Donato was also the subject of some discussion, as was the use of analogue computers by Segrè.

In the sessions on hormone labelling it was soon apparent that a greater degree of protein modification is permissible and altogether higher specific activities are required. Some seventeen hormones can now be estimated by radioimmunoassay, and Yalow (New York) considered the

general principles underlying the procedures used, drawing on the extensive experience of the New York group using insulin, growth hormone, ACTH and parathyroid hormone. Requirements of the labelled hormones were regarded as less stringent than is widely supposed, the essential one being that the plasma hormone and a standard preparation should be equivalent in their capacity to inhibit the reaction between labelled hormone and antiserum. It follows that neither the animal species from which the standard preparation, or the preparation for iodination, is obtained nor, within limits, the degree of damage suffered during iodination is critical. There was general agreement, however, that some purification of the labelled hormone is essential and methods for doing this were described. The possibility that metabolic fragments of endogenous hormones which are immunologically but not hormonally active might be present in plasma was also discussed. The general problem of damage to hormones was included in a round-table session organized by Milhaud (Paris).

Some fifteen successful assays using the chloramine *T* method have been carried out in various laboratories, but Greenwood (London) referred to unsatisfactory experiences with iodine-131 obtained since 1964. Results with the method in the United States had been more consistent than those obtained elsewhere and this seemed to depend mainly on higher specific activities of the available iodine-131. Michel (Paris), Quabbe (Berlin), Brauman (Brussels) and Franchimont (Liège) had broadly shared Greenwood's experience. The determination of ^{131}I-specific activities was outlined by Yalow. In view of the lack of knowledge of iodine and radioiodine chemistry emphasized by Hughes any improvement in the precision of micro-iodine estimations must be welcomed.

The availability of standard preparations of human growth hormone and antisera was discussed by various speakers including Coates (London) and Stewart (Frankfurt). Rosa (Pisa) and Ooms (Brussels) presented short communications on the immunological and biological properties of radioiodinated insulins, while Melani (Frankfurt) reported a procedure for assaying adrenocorticotrophic hormone (ACTH) which depends on the use of an ion exchange resin. The sensitivity of his assay was equivalent to that of the first ACTH one reported by Berson *et al.*, and this has since been greatly increased. Crosignani and Polvani (Milan) and Freedlender (Boston) reported on assays for human chorionic gonadotrophin and growth hormone respectively which differed in detail from previous assays using the double antibody method. Franchimont (Liège) outlined assays both for human follicle-stimulating hormone and luteinizing hormone, and reported millimicrogram levels during the normal menstrual cycle with two peaks of luteinizing hormone and one of follicle-stimulating hormone. A full report of his procedure is awaited with considerable interest.

In 1963 groups in New York and Washington jointly reported an assay for parathyroid hormone, the procedure having since been improved in sensitivity and applied to humans and animals. Yalow summarized the present position of the New York group and gave unpublished results of human plasma measurements from which it was evident that clinical application of the method is still hindered by its lack of sensitivity. Potts, on behalf of the Washington group, showed data bearing on the control of animal secretion of the hormone. In the course of this work an identical reaction between crude human parathyroid hormone and purified bovine parathyroid hormone was demonstrated. Availability of purified bovine hormone and antiserum was also discussed.

The clinical and physiological applications of radioimmunoassays were only outlined for insulin by Samols (London) and for glucagon by Weinges (Homburg-Saar) representing Unger's group. Both communications served *inter alia* to emphasize the usefulness of procedures which can be carried out at rates of up to 200 measurements per week. A discrepancy was noted in the levels of glucagon found in plasma by Samols and Unger, and this may explain the differences in their results after oral administration of glucose.

Abstracts of the papers presented are available (*J. Labelled Comp.*, 1, No. 4, 311) and a full report in book form will appear in due course.

DOMESTIC FOOD CONSUMPTION AND EXPENDITURE

DOMESTIC Food Consumption and Expenditure, 1963, is the fourteenth annual report produced by the National Food Survey Committee*. The 1962 report reviewed the findings of surveys conducted during the years 1950–60. Over such a period it is easier to observe changing trends in consumption patterns and the quantities of food consumed or purchased than from one year to the next. Nevertheless, interesting facts do emerge from the present report.

Survey methods remained unchanged, but for reasons of economy the sample in the 1963 survey was reduced by 18 per cent as compared with the 1962 sample, the effective size being 7,532 households. There was no change in the average number of persons per household, which again was least in London (2·95) and highest in rural areas (3·41). Because of random sampling, rural areas were over-represented in the 1963 survey, and in order to correct this bias the national averages in this report have been obtained by weighting the separate averages for the different types of urban and rural areas by the estimated population resident in those areas. The composition of the population is interesting. In social class *A* there were only eight households with four or more children and only very cautious conclusions can be drawn from this sample. The representation of old-age pensioners, of whom two-thirds were women, further increased. It appears that the highest proportion of elderly men live in the south-west region. The average number of earners per household tended to vary inversely with the income of heads of households including a number of children, and adult earners tended to be fewer in Class *D* than in any other earning classes because of the smaller average number of adults per household. The highest number of earners was in families containing adolescents.

The exceptional severity of the 1963 winter adversely affected the supply and distribution of certain foods and this in turn affected prices during the first quarter of the year. Over the year, and for the country as a whole, the average total expenditure was 32*s*. 4*d*. per week, a slight increase over 1962, which can be explained partly by a rise in food prices and partly by an increase in the quantity of food purchases. Expenditure on 'convenience foods' rose to 6*s*. 1*d*. per head per week as compared with 5*s*. 11*d*. in 1962, but remained at about 19 per cent of the household food budget. Consumption of dairy products and eggs increased, while the consumption of fish fell. Consumption of poultry increased, though at a slower rate than previously, probably at the expense of meat, the

* Ministry of Agriculture, Fisheries and Food *Domestic Food Consumption and Expenditure. 1963—Annual Report of the National Food Survey Committee.* Pp. ix+131. (London H M S O, 1965.) 12*s*. 6*d* net.

consumption of which showed a slight decrease. The demand for tea remains inelastic, in spite of changes in price or income, but the demand for coffee has risen, particularly for 'instant coffee', purchases of which were nearly 80 per cent higher than in 1960.

The tables showing the expenditure on and consumption of food are informative. Expenditure per week was highest (50*s*. 3*d*.) in class *A* for families containing two adults under 55, falling to 27*s*. 4*d*. for a family with three children; it was lowest in classes *C* and *D*, where 19*s*. 9*d*. was spent by the family with four or more children. The lowest consumption per head per week of a high proportion of foods was most frequently recorded in families with four or more children; for bread, vegetables and beverages, such as tea, however, families with two or three children occupied this position. For all foods except tea taken by families of two adults over 55, the highest consumers consisted of families of two adults under 55. With respect to differences in social classes, class *A* were, as might be expected, the highest consumers of the more expensive foods such as dairy produce, eggs, meat, chicken, fish and coffee, whereas old-age pensioners led with tea and sugar, and class *C* with vegetables. The cheaper foods, bread and cereals, sugar and tea, were taken in the smallest quantity by class *A*, whereas classes *C* and *D* consumed less of all the other food groups, being joined by the old-age pensioners in the low consumption of meat and fruit.

The energy value of the diet of the average person remains much the same as in 1962, with class *A* and old-age pensioners having the highest intake of calories. The percentage of calories provided by protein remains unchanged at 11·5 per cent. The level of intake of other nutrients in families appeared satisfactory when expressed as a percentage of recommended requirements, but this may not apply to all individuals. The way in which food is distributed within the family is unknown, and possibly some members of some families were abundantly fed at the expense of others. MARGARET E. CAMERON

ABUNDANCE ANALYSIS OF THE PECULIAR STAR *HD* 101065

By DR. A. PRZYBYLSKI
Mount Stromlo Observatory, Australian National University, Canberra

THE eighth magnitude star *HD* 101065 ($\alpha = 11h\ 35{\cdot}2m$, $\delta = -46°\ 26'$, 1950·0) has a unique and extremely peculiar spectrum[1-4]. While spectral peculiarities are superimposed on a more or less normal spectrum in other abnormal stars, there are scarcely any normal features in the spectrum of this star. Most striking is the absence of the elements usually seen in the spectra of normal stars such as iron, titanium, chromium, manganese and sodium, and the great strength of lines of barium and the rare earths. Hydrogen, calcium, barium and possibly strontium and lithium are the only elements which can be seen in the spectrum besides the ionized rare earths. The hydrogen lines are of normal width but they are much shallower than in a normal star of similar temperature. The calcium *H* and *K* lines are sharp and are weaker than many strong lines of the rare earths. The *K* line, with its equivalent width of 0·3 Å, is about sixty times weaker than in the solar spectrum even though we are dealing with a star of similar temperature.

Counting each local minimum of intensity as a separate line, about 3,000 lines have been measured between λ3600 and λ4950 Å on plates with a dispersion of 6·7 Å/mm. The effect of mutual blending of lines is very large and the true continuum is probably not seen at all in the whole spectral region below 5000 Å.

Normally the number of lines decreases with the increasing wave-length and for this reason the red region of the spectrum should be easier to analyse. Unfortunately, high dispersion spectra of *HD* 101065 in the red region are beyond the reach of existing southern telescopes. Only one spectrum of the visual region with a dispersion of 20 Å/mm has been obtained at Mount Stromlo Observatory, but it is of poor quality. For this reason only limited use of this spectrum is made in the present article. It is hoped that in the near future better spectra will be obtained in the visual range. The present results are based mostly on the best spectrum obtained in the photographic region. Its width is 0·35 mm and its dispersion 6·7 Å/mm. The projected slit width is 28μ.

The effective temperature of *HD* 101065 derived from *B*, *G*, *R*, *I* colours of the six-colour photometry by G. E. Kron and K. C. Gordon[2] is 6,350° K. However, if it is taken into account that the two other colours *U* and *V* show the largest known ultra-violet deficiency of 0·4 magnitudes, this temperature should be lowered by about 400 degrees. In the present investigations it has been assumed that the effective temperature of *HD* 101065 is identical with that of the Sun (5,900° K).

The parallax of the star is unknown but a fairly high proper motion of 0·054″ per annum, coupled with the low radial velocity of the star (+10 km/sec), seems to indicate that the star is not far from the main sequence. It is unlikely that it is a supergiant although it could possibly be a giant of absolute magnitude +1. However, it is most likely a dwarf on the main sequence and therefore physical parameters of the solar atmosphere used by L. H. Aller[5] have been assumed in the analysis (the reciprocal temperature $\theta = 0{\cdot}9$ and the logarithm of the electron pressure $\log p_e = 0{\cdot}9$). No estimate of the electron pressure from the spectrum is possible since no element is seen in two stages of ionization.

In view of the fact that *HD* 101065 is an abnormal star, the possibility that some unknown sources of opacity influence its atmosphere cannot be excluded. On the other hand, the agreement of its *B*, *G*, *R* and *I* colours with those of normal late *F* type dwarfs suggests that its main source of opacity is the negative hydrogen ion. This has been assumed in the present investigations, since scarcely any other assumptions could properly be justified.

Because of severe mutual blending, very few spectral lines are suitable for an analysis of the spectrum. Only 350 lines of fifteen elements could be used for the abundance analysis. It should be emphasized that almost all equivalent width determinations are only crude estimates which would be disregarded in the analysis of a normal star. However, in view of the importance of *HD* 101065 for the theory of stellar evolution, even an analysis of the chemical composition of its atmosphere based on poor data is certainly better than pure guesswork or complete uncertainty.

In spite of the difficulties in the measurement of the equivalent widths, the individual points on the curve of growth diagrams do not show an obviously larger scatter than on diagrams for normal stars. This may give a certain confidence in the results of the analysis, but does not exclude the possibility of systematic errors in the measurements of the equivalent widths. These errors may be due partly to the error in the continuum (which has been drawn through the highest intensity peaks), partly to the contribution of lines which have not yet been catalogued, and partly to the method used in order to eliminate the effect of blending by neighbouring lines.

Neighbouring lines have been separated by drawing straight lines perpendicular to the dispersion on the tracing through the intensity peaks. In all probability the equivalent width of faint lines has been overestimated.

A coarse analysis of the star was carried out using Wrubel's curve of growth. The most reliable curve has been obtained for cerium for which the largest number of lines was available. This curve gave the best determination of the turbulent velocity of 5 km/sec which was afterwards used for all other elements. This fixing of the turbulent velocity permitted a better determination of abundances since it removed one source of uncertainty in the position of the theoretical curve of growth superimposed on the stellar curve of growth diagram.

The values of the oscillator strength were taken from Corliss and Bozman's monograph[6]. Unfortunately no data are available for holmium and terbium. However, it was possible to evaluate at least approximately the spectroscopic data entering into the abscissae of the curve of growth from the intensities of lines tabulated by Meggers, Corliss and Scribner[7]. The additional error caused by this approximate procedure is probably less than 0·1 in the logarithm of the abundances. The same method was also used for erbium and thulium, since oscillator strengths were available only for a small number of lines of these elements. The determination of the abundance of thulium from lines with no known *gf*-values leads to practically the same result as the determination from lines with known oscillator strengths.

The results of the analysis are shown in Table 1. They are normalized to the logarithm of hydrogen abundance 12·0. The last column of Table 1 shows the over- or under-abundance of elements in comparison with Suess and Urey's[8] cosmic abundances.

Table 1

Element	Log abundance	Δ Log abundance
Hydrogen	12·0	—
Calcium	2·4	−3·8
Strontium	3·4	+0·6
Barium	3·6	+1·5
Lanthanum	3·7	+1·9
Cerium	4·0	+2·1
Praseodymium	4·0	+2·9
Neodymium	4·1	+2·4
Samarium	4·0	+2·7
Europium	4·0	+3·2
Gadolinium	4·0	+2·7
Terbium	3·5	+3 0
Dysprosium	3·5	+2·2
Holmium	3·8	+3·2
Erbium	3·7	+2·7
Thulium	3·6	+3·6

The abundance of calcium is based on only one line (*K* line at λ3933 Å) since the *H* line at λ3968 Å is blended with a strong line of dysprosium. However, the determination of calcium seems to be quite reliable. The abundance of strontium is based on two lines at λ4215 Å and λ4161 Å, but the possibility cannot be excluded that these lines may be wrongly identified. The strontium line at λ4077 Å is in a wide blend and cannot be used even for a positive confirmation of the presence of this element in the atmosphere of *HD* 101065. Strontium is included in Table 1 because the line at λ4215·42 Å (differing by 0·1 Å from the laboratory value) cannot be identified as a known line of a rare-earth element.

The over-abundances of barium and lanthanum seem to be higher than in peculiar *A* stars of Cr–Eu type but they are lower than the over-abundances of the rare earths following lanthanum. The spectrum of *HD* 101065 shows very strong lines of holmium for which no abundance determination in stars is yet available. However, holmium lines seem to be a common feature in Cr–Eu stars.

No conclusive evidence for the presence of the two heaviest rare earth elements (ytterbium and lutetium) in the atmosphere of the star is available. A good spectrogram in the red region would certainly solve this question for lutetium, which has a number of strong lines in this part of the spectrum, but for ytterbium the answer may be more difficult.

The spectrum of the star in the visual range seems to indicate the presence of a lithium line at λ6707 Å, but this spectrum is of poor quality and does not permit precise determination of the wavelength of this line. Anyhow this line would be blended with a fairly strong line of samarium. It is hoped that future observations in the red region will definitely settle the question of whether lithium is present in the spectrum or not. This is an extremely important question since the presence of lithium would mean that the disappearance of many elements in the spectrum of the star may be due to the destruction of these elements as the result of surface activity. Lithium and other light elements are the debris of the destruction of heavy elements through bombardment by high-energy protons.

A very faint line at λ4057·8 Å could possibly be due to neutral lead. If this identification is correct the logarithm of the abundance of neutral lead would be −0·6 on the scale adopted in Table 1. Adding the abundance of ionized lead obtained from Saha's equation we obtain 1·1 as the logarithm of total abundance of this element. However, the identification of the line of λ4057·8 as coming from PbI is rather doubtful.

No lines of iron could be identified in the spectrum of the star. This could be due to the fact that sometimes strong lines of the rare earths coincide with iron lines. However, the absence of two neutral lines at λ3820·43 Å and λ4045·82 Å, which do not coincide with known rare-earth lines, is a well-established fact. Assuming that any possible iron line at λ4045·82 Å has an equivalent width of less than 20 mÅ we obtain +1·1 as the highest possible logarithmic abundance of neutral iron. The total logarithmic abundance of iron on the scale of Table 1 would then be 2·5, which is 4·8 less than the cosmic abundance of iron according to Suess and Urey[8]. If Aller's abundances are taken for comparison the under-abundance of iron would be lower (Δlog abundance = −4·1), but other elements listed in Table 1 would show no significant differences in their over- or under-abundances.

Adding all the abundances of metals shown in Table 1 we obtain log $N = 5{\cdot}0$ as the total abundance of metals which are represented by lines in the spectrum of the star. This is 2·3 less than Suess and Urey's[8] logarithmic abundance of iron. *HD* 101065 may therefore be a metal-poor star in spite of its extremely high blanketing effect and its highest known Strömgren metallic line index for any *F* or *G* star (B. Westerlund, private communication). Unfortunately a definitive determination of the metal content in the atmosphere of the star would require the knowledge of the abundances of elements which are not represented in the Fraunhofer spectrum of the star.

If *HD* 101065 is a metal-poor star, the adopted value of the logarithm of electron pressure may be too high, which would also mean that the opacity used in the analysis is too high. The results shown in Table 1 should be reduced by 0·3 if the star is as poor in metals as the sub-dwarf *HD* 140283. They should be lowered still more by about 0·5 if *HD* 101065 is a metal-poor giant. Unfortunately the spectrum of the star contains no features which could be used for the determination of the electron pressure in its atmosphere. It should be borne in mind that, although the absolute abundances shown in Table 1 are valid only for the adopted value of electron pressure, the relative abundances of the rare earths should be quite reliable within the limits of accuracy of the curve of growth method.

The present analysis was made during my stay at the Royal Greenwich Observatory and later at Mt. Wilson and Palomar Observatories. I thank the Astronomer Royal, Sir Richard v.d. R. Woolley, and Dr. H. W. Babcock for their hospitality. I thank Prof. B. J. Bok,

POSITIONS OF RADIO SOURCES MEASURED WITH THE ONE-MILE RADIO TELESCOPE

By E. A. PARKER, B. ELSMORE and DR. J. R. SHAKESHAFT
Mullard Radio Astronomy Observatory, Cavendish Laboratory, Cambridge

THE one-mile radio telescope[1] at the Mullard Radio Astronomy Observatory, Cambridge, is being used in a continuing programme to study radio galaxies[2] and other sources. This article reports measurements of the positions of twenty-two lesser-known sources of which all but two are unresolved by the 23″ beam of the telescope at 1,407 Mc/s. Observations of extended and double sources will be discussed elsewhere[3]. The positions have been examined on the prints of the Palomar *Sky Survey* and for many of the sources there are coincident optical objects. The accuracy of the radio positions is such that these objects are almost certainly associated with the radio emission.

The measurements involve continuous observation of each source for a 12-h period using three 60-ft. paraboloidal reflectors on an east–west axis. Four simultaneous outputs are obtained, corresponding to interferometers of two different spacings and at two wave-lengths, 73 cm and 21·3 cm, but in general the most accurate positions for unresolved sources are those measured with the largest available spacing, 1·6 km. at the shortest wavelength, 21·3 cm.

To reduce the observations a position of the source is assumed and the expected variation of phase difference of the signals arriving at the two aerials of each interferometer pair is calculated for the 12-h period. This is then

Table 1

	Radio position	Optical position	Notes
3C 14	00 h 33 m 29·46 s 18° 21′ 32·4″		A faint diffuse object, visible only on the red print, lies within a few sec of arc of the source
3C 16	00 h 35 m 08 53 s 13° 08′ 34·1″		Nothing is visible within 13″ of the source
3C 19	00 h 38 m 13·88 s 32° 53′ 42·9″		There is no object brighter than 20 m within 10″ of the source. See also Adgie and Gent (ref. 5)
3C 20	00 h 40 m 20·30 s 51° 47′ 10·2″	00 h 40 m 20 46 s ±0·25 s 51° 47′ 08″ ±3″	A pair of 19 m red galaxies separated by 6″ lies close to the source, which is slightly extended. The optical position (Parker) is that of the S. following member. An almost stellar 18·5 m object follows this by 8″. See also Adgie and Gent (ref. 5)
3C 93·1	03 h 45 m 35·76 s 33° 44′ 08·5″	03 h 45 m 35·95 s ±0·25 s 33° 44′ 07″ ±3″	The optical position (Parker) is that of a 19·5 m red galaxy in a cluster. The source scintillates (ref. 6), indicating structure <1″
3C 153	06 h 05 m 44·56 s 48° 04′ 52·8″	06 h 05 m 44·55 s ±0·15 s 48° 04′ 49·0″ ±1·0″	The optical position (Parker) is that of the diffuse red 18·5 m object noted by Longair (ref. 4). See also Adgie and Gent (ref. 5)
3C 173	06 h 58 m 56·41 s 38° 01′ 46·0″		There is nothing visible in the position of the radio source which lies 11″ S. following a 14 m star
3C 213·1	08 h 58 m 05·02 s 29° 13′ 35·5″	08 h 58 m 05·3 s ±0·3 s 29° 13′ 38″ ±4″	The optical position (Parker) is that of a 17·5 m object, probably a compact galaxy. The red image is almost stellar but on the blue print the object is more diffuse and fainter.
3C 241	10 h 19 m 09·36 s 22° 14′ 44·2″		Nothing is visible within 50″ of the source which scintillates (ref 7), indicating structure <1″. See also Adgie and Gent (ref. 5)
3C 256	11 h 18 m 04·22 s 23° 44′ 23·2″		Nothing is visible within 20″ of the source which follows the galaxy 'a' in Longair's finding chart (ref. 4) by 29″. The source scintillates (ref. 6), indicating structure <1″. See also Adgie and Gent (ref 5)
3C 258	11 h 22 m 06·23 s 19° 36′ 05·4″	11 h 22 m 06·4 s ±0·3 s 19° 35′ 59″ ±4″	The optical position (Parker) is that of a 19 m object. Its red image is irregular in outline but the blue image is brighter and more star-like. The radio source may be slightly extended
4C 31 38	11 h 53 m 44·27 s 31° 44′ 43·8″	11 h 53 m 44 22 s ±0 15 s 31° 44′ 44″ ±2″	The optical position (Parker) is that of an 18 m blue object. It appears stellar on the blue print but fainter and diffuse on the red print. Nothing else is visible within 30″
3C 268 3	12 h 03 m 54·19 s 64° 30′ 18·2″		A very faint diffuse object lies at the radio position with others within 10″, probably a distant cluster of galaxies
3C 268·4	12 h 06 m 41·90 s 43° 56′ 00·0″	12 h 06 m 42·1 s ±0·1 s 43° 56′ 02″ ±2″	The optical position (Parker) is that ot an 18 m stellar object; equally bright on the red and blue prints. Some faint nebulosity extends about 10″ N from it See also Adgie and Gent (ref. 5)
3C 270·1	12 h 18 m 03·98 s 33° 59′ 49·2″	12 h 18 m 04 00 s 33° 59′ 50·0″	The optical position (Veron (ref. 8)) is that of a quasi-stellar source (refs. 2, 8)
3C 277·1	12 h 50 m 15·35 s 56° 50′ 36·3″	12 h 50 m 15·31 s 56° 50′ 37·0″	The optical position (Veron (ref. 8)) is that of a quasi-stellar source (refs. 2, 8) According to Sandage *et al.* the photo-electric colours do not eliminate the possibility that the optical object is a blue star, but the positional agreement found here strongly suggests that it is nevertheless the radio source
3C 288 1	13 h 40 m 29·98 s 60° 36′ 47·9″	13 h 40 m 30·2 s ±0·2 s 60° 36′ 50″ ±3″	The optical position (Parker) is that of an 18 m blue stellar object noted previously (ref. 9). Faint blue nebulosity extends about 5″ E. from the image
3C 309·1	14 h 58 m 57·62 s 71° 52′ 11·3″	14 h 58 m 57·8 s ±0·15 s 71° 52′ 12·0″ ±1″	The optical position (Parker) is that of a 17 m blue stellar object (ref. 2), probably a quasi-stellar radio source
3C 318	15 h 17 m 50 68 s 20° 26′ 51·2″	15 h 17 m 50·5 s ±0 2 s 20° 26′ 52″ ±3″	The optical position (Parker) is that of a 19·5 m object, equally bright in red and blue. It is shown on a finding-chart by Longair (ref. 4), immediately following and S. of the pair of objects 'a'. Other faint red objects are nearby. The source scintillates (ref 6), indicating structure <1″. See also Adgie and Gent (ref. 5)
3C 454	22 h 49 m 07·85 s 18° 32′ 49·9″	22 h 49 m 07·77 s ±0 1 s 18° 32′ 46·1″ ±1″	The optical position (Parker) is that of an 18 m blue stellar object (refs. 2, 5). Schmidt (ref. 10) has obtained a spectrum showing it to be a quasi-stellar radio source with a very large red-shift. The source scintillates (ref. 6), indicating structure <1″. See also Adgie and Gent (ref. 5)
3C 454 3	22 h 51 m 29·54 s 15° 52′ 58·5″	22 h 51 m 29·45 s ±0·1 s 15° 52′ 53·1″ ±1″	The optical position (Parker) is that of a 16 m stellar object, equally bright on the red and blue prints. A similar object with a faint companion lies 12″ N. The source scintillates (ref. 6), indicating structure <1″
3C 460	23 h 18 m 59·77 s 23° 30′ 24·7″	23 h 18 m 59 8 s ±0 1 s 23° 30′ 21″ ±1·5″	The optical position (Parker) is that of an 18 m red galaxy, object 'a' of Wills and Parker (ref. 9). See also Adgie and Gent (ref. 5)

compared in a computer with the observed phase variation and the difference between the two, together with the observed intensity of the source, is automatically plotted out as a function of time for the 12-h run. From these curves it is possible to determine independently the difference in R.A. and declination between the true and assumed positions, as will be explained in detail elsewhere. Small corrections are necessary for ionospheric refraction.

If the relative positions of the aerials are known sufficiently accurately by surveying, then the source positions may be determined absolutely with an accuracy limited only by the uncertainties in these values, by the effects of system noise, and by deflexions caused by other confusing sources within the reception pattern. In practice, however, it has been found that there is a systematic discrepancy of a few seconds of arc between the accurate positions of well-known optical objects and the corresponding radio source positions derived absolutely. The cause of this discrepancy is not yet clear and the positions listed in this article are based on the geometry of the instrument derived from this comparison of radio and optical positions rather than that found from surveying. The probable errors of the radio positions are determined by the uncertainties in this calibration procedure and are $\pm 0{\cdot}1$s in right ascension and $\pm 1'' \times \operatorname{cosec} \delta$ in declination. Quite apart from any real differences which there may be between optical and radio positions, these errors are generally larger than those of which the instrument is now capable. This is because the observations have been spread over the past 18 months, during which time there have been considerable improvements in the phase stability of preamplifiers and temperature compensation of radio-frequency cables.

The field of each source has been examined on *Sky Survey* prints making use of a transparent overlay[4] to locate the radio position.

Notes on the associated optical objects and, in many cases, their positions measured by means of a travelling microscope are given in Table 1. Since only the *Sky Survey* prints were available to us these optical positions are not so accurate as they might be had the original plates been used.

When this work was nearly completed positions of some of the sources with a comparable accuracy were sent to us privately by Adgie and Gent[5]. In nearly every case these agree well with the positions in Table 1. Some of the objects have been identified independently by Veron (ref. Adgie and Gent[5]). J. D. Wyndham (private communication) and T. A. Matthews (private communication) have also noted some as possible or probable identifications on the basis of less accurate radio positions.

We thank Prof. Martin Ryle for his advice and G. Macdonald and other colleagues for assistance.

ETHYLENE PRODUCTION FROM LINOLENIC ACID

By F. B. ABELES
U.S. Army Biological Laboratories, Fort Detrick, Frederick, Maryland

LIEBERMAN and Mapson[1] have shown that linolenic acid may serve as a precursor of ethylene. The possibility that the ethylene that is evolved from plants arises from linolenic acid was investigated by determining the relationship between ethylene evolution and linolenic acid levels from a number of plants.

Ethylene production from linolenic acid was measured in a manner similar to one described earlier[2]. The fatty acid peroxides were measured according to the methods of Dahle *et al.*[3]. Extraction and measurement of fatty acids from plants followed the method of Huston and Albro[4]. Ethylene evolution from intact plants was measured by placing material into 3-l. containers and withdrawing samples of gas after 20 h. Measurement of ethylene by gas chromatography has also been described earlier[5]. Etiolated beans (*Phaseolus vulgaris* L. var. red kidney) and peas (*Pisum sativum* L. var. 'Alaska') were grown in the dark for a week at 25° C and 80 per cent relative humidity. Apples (*Malus pumila* Mill. var. 'Eastern Delicious') were obtained from local markets.

Fig. 1 is a representative experiment showing the production of ethylene from peroxidized methyl linolenate. Other hydrocarbon gases such as ethane and propane, and a number of unidentified peaks were also produced. The presence or absence of a methyl group on the fatty acid has no effect on ethylene production. Under the conditions shown in Fig. 1, the amount of ethylene evolved after 24 h represents a 0·2 per cent yield on a mole of ethylene per mole of peroxidized linolenate basis. The effect of ascorbate as a catalyst could be duplicated by 0·1 mg of a crude pea protein fraction described earlier[2] or similar amounts of lipoxidase. In these cases the activity of the protein was destroyed by heating. Addition of 1 μmole of potassium cyanide and 0·25 μmole of ethylenediamine tetraacetic acid inhibited gas production. A *p*H optimum between 7 and 8 was obtained with phosphate buffer. Other buffers, such as pyrophosphate, *tris* hydroxy methyl amino methane, and glycylglycine lowered the rate of gas production.

The possibility that ethylene production from peroxidized linolenate was mediated by means of a free radical mechanism was tested by the addition of 10 μmoles of catechol of iodine. Both these substances are known to quench free radical reactions by preferentially trapping the unpaired electrons. Both catechol and iodine inhibited ethylene production from pea protein and ascorbate-catalysed reactions. Reaction inhibition was about 70 per cent for the pea protein and about 85 per cent for the ascorbate.

Other fatty acids were examined for their ability to serve as a substrate for this reaction. Stearic, oleic, linoleic, and arachidonic were found to be inactive. However, a C_{22} fatty acid from herring oil, clupanodonic acid, was found to be active. The similarity between this compound and linolenic acid is the presence of a terminal CH_3—CH_2—CH= group at the methyl carbon end of the chain. On the premise that this particular end-group accounts for the activity of linolenic acid, other compounds having the same structure were examined. 2-Pentenoic acid, 3-hexenoic acid, and 3-heptene were also active as a source of ethylene. Under conditions identical to those in Fig. 1, ethylene production from these compounds was in the order of 1 nl. ethylene after 30 min.

Levels of linolenic acid and rates of ethylene production from apples were determined to explore the suggestion of Lieberman and Mapson[1] that ethylene production from

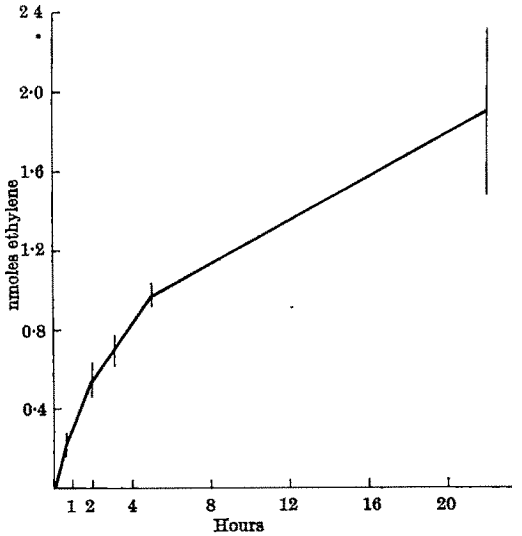

Fig. 1. Ethylene production from peroxidized linolenic acid. 0·88 μmole peroxidized (0·06 mole oxygen/mole fatty acid) linolenic acid, 50 μmoles sodium ascorbate, 125 μmoles potassium phosphate buffer, *p*H 7·3, liquid vol. 2·5 ml., helium gas phase, 25° C. Vertical lines indicate extent of standard error

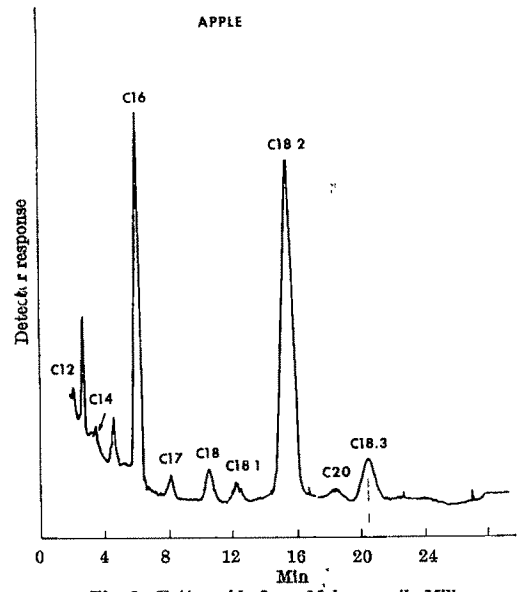

Fig. 2. Fatty acids from *Malus pumila* Mill

apples may arise from linolenic acid. Market apples were peeled, cored, and sliced into quarter sections. Two slices were stored in a refrigerator and the other two placed in a container and the ethylene evolution measured after 20 h. A representative chromatogram of the fatty acids extracted from apples is shown in Fig 2. The data from two experiments in Table 1 indicate that the linolenic acid content of apples remains approximately constant during this 24-h period. The gas produced during this time is equivalent to about 20 per cent of the linolenic acid content. If linolenic acid is the source of ethylene in this tissue then the reaction is far more efficient in apples than *in vitro*. The data also indicate that the amount of linolenate does not change greatly during the period of time ethylene production was measured and also that a C_{18} fatty acid with two double bonds is not present in the

fatty acids extracted from the apple. If ethylene does arise from linolenic acid it does so from a small pool of activated (peroxidized) acid, the level of which is maintained by a rapid turnover of the activated fatty acid.

Naphthaleneacetic acid (NAA) is known to stimulate ethylene production from peas and beans[5]. It was of interest, then, to determine if increased rates of ethylene production would have any effect on linolenic acid levels from plants treated with NAA. Week-old etiolated pea and bean (cotyledons removed) plants were sprayed with 2×10^{-3} M NAA until run off. Treated plants and controls were placed in containers for 20 h, after which time ethylene evolution was measured and fatty acids were extracted. Representative chromatograms of the fatty acids of these plants are shown in Figs. 2 and 3. No significant change was noted in the levels of any particular fatty acid between treated and control plants. Although care was taken to ensure that the extraction of fatty acids was quantitative, it was not possible to tell if changes in ethylene production between treated and controls were reflected in levels of linolenic acid (Table 2).

Table 2. COMPARISON OF LINOLENIC ACID LEVELS AND ETHYLENE PRODUCTION FROM NAA-TREATED PLANTS

Experimental material	nmoles linolenic acid		nmoles ethylene 20 h	
	g fresh weight		g fresh weight	
	Control	2×10^{-5} M NAA	Control	2×10^{-5} M NAA
Pisum sativum L.	340	130	0·05	7·1
Pisum sativum L.	140	260	0·05	2 2
Phaseolus vulgaris L.	570	480	0·18	14

The results with clupanodonic acid and other compounds containing terminal $CH_3—CH_2—CH=$ groups indicated that the activity of linolenic acid is due only to this particular configuration. The possibility that ethylene may arise from this particular type of structure in Nature remains open. Observing that a variety of other compounds such as ethylene oxide, diethyl ether, ethanol, and methionine have been reported[1] to produce ethylene suggests other alternatives. Any scheme that postulates linolenic acid as a precursor of ethylene in apples is unattractive because, first, the *in vivo* reaction is inefficient (0·02 per cent after 20 h) and the ratio of ethylene production to linolenic acid levels in apple is high (20 per cent after 20 h), and second, no C_{16} fatty acid with two double bonds occurs in apple tissue. The fact that linolenic acid must be peroxidized[1] before it serves as a source of ethylene raises the question of whether fatty acid peroxides occur in normal tissues. Desai and Tappel[6] have shown that enzymes and subcellular particles are damaged by peroxidized fatty acids. However, there are numerous reports that peroxidized fats do occur *in vivo*[7].

In conclusion, the evidence indicates that linolenic acid does not serve as a precursor of ethylene. Final proof of this depends on measurements of rates of linolenic acid turnover and the extent to which peroxidized linolenic acid occurs in Nature.

ROLE OF THE AMINO-ACID 'CODE' AND OF SELECTION FOR CONFORMATION IN THE EVOLUTION OF PROTEINS

By DR. CHARLES J. EPSTEIN

Laboratory of Chemical Biology, National Institute of Arthritis and Metabolic Diseases, National Institutes of Health, Bethesda, Maryland

I WAS able to show in a previous communication[1] that homologous positions in a series of evolutionarily related proteins (the same protein in different species, or proteins resulting from duplicated genes in the same or related species) tend to be occupied by amino-acids which are related by the nature of their side-chains. Certain sites in an amino-acid sequence are usually occupied by polar amino-acids, while others are generally occupied by non-polar amino-acids. This type of distribution is readily understood if it is assumed, first, that the folded (tertiary) structure of the molecule is determined by its amino-acid sequence[2], and, second, that hydrophobic groups reside predominantly in the interior of the molecule while polar groups are on the outside. The latter assumption was initially based on the predictions of Kauzmann[3] and on the X-ray diffraction studies of myoglobin by Kendrew[4]. Detailed analysis of the conformations and sequences of several haemoglobins and myoglobins have recently been published by Perutz[5] and by Perutz, Kendrew and Watson[6]. Their results again demonstrate that the interiors of these molecules are almost completely hydrophobic in character and that virtually all polar groups are at the surfaces. Hydrophobic groups are also found at or near the surface, although these residues are quite often alanine. In several instances, surface hydrophobic groups appear to be involved in interchain bonds, a situation predicted by Fisher[7]. Investigation of the three-dimensional structure of egg-white lysozyme has indicated that the separation between the interior and the exterior of a molecule may not be so definite as the structures of the haem proteins suggested[8]. However, as a working rule it seems reasonable to assign surface positions to the polar residues and interior positions to at least a large number of the hydrophobic residues of a molecule (glycine and alanine do not appear to prefer either location).

On the basis of initial comparisons, the hypothesis was advanced that the necessity to preserve correct three-dimensional structures by the maintenance of particular distributions of hydrophobic and polar residues in their amino-acid sequences is an important factor in guiding the 'evolution' of protein sequences. What was not known were the relative importance of the amino-acid code itself, independent of selection, and of subsequent natural selection in preserving these distributions of residues. It had already been pointed out that related amino-acids (related in terms of the nature of their side-chains or of their biosynthetic precursors) often had similar RNA codons[9], but only with the development of an ordered code could the full significance of this observation be determined. The sixty-four codon triplets listed by Nirenberg *et al.*[10] can be conveniently represented in the three-dimensional matrix schematized in Fig. 1. A single-step mutation results in movement from one position to another along one of the three orthogonal axes—diagonals are not allowed. Two-step mutations involve movement within a horizontal or vertical plane; three-step mutations can, of course, result in movement between any two places in the matrix. As is readily apparent from the interrelationships depicted in Fig. 1, and as has already been noted by others[11–13], there are several groups of related amino-acids which can change from one to another by single-step mutations. For example, phenylalanine, leucine, isoleucine and valine can be interconverted by single mutations in the first nucleotide of the triplet, as can, likewise, leucine, methionine and valine; tyrosine, histidine, asparagine and aspartic acid; and glutamine, lysine and glutamic acid. Changes in the third nucleotide can accomplish shifts from asparagine to lysine, aspartic acid to glutamic acid, and histidine to glutamine, while shifts in the second can produce such interchanges as phenylalanine and tyrosine, alanine and glycine, and histidine and arginine. On the other hand, certain interchanges that might on *a priori* grounds be expected to be readily accomplished—such as of the basic amino-acids, lysine and histidine, or of the aromatic residues, tryptophan and tyrosine—cannot be accounted for by single-step mutations.

If it is assumed that all triplets (except those for 'termination') will code for an amino-acid and that mutations at any position in the triplet and from any one

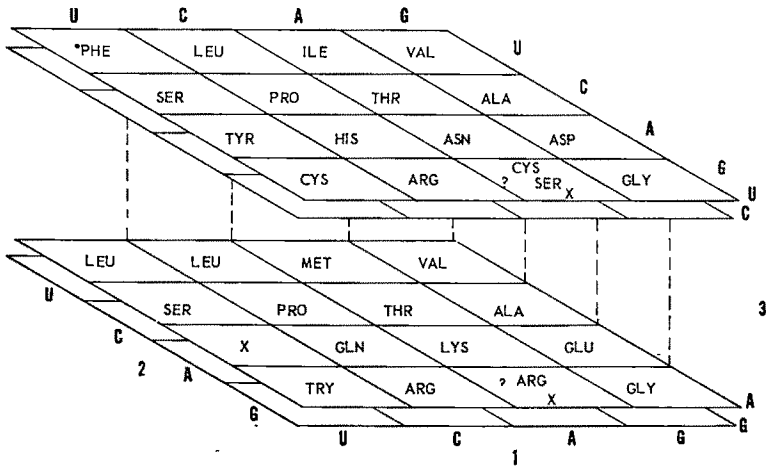

Fig. 1. The amino-acid 'code', adapted from the table of Brimacombe *et al.* (ref. 10). Each axis of the 'grid' represents a different base in the codon 'triplet'. Since there appears to be degeneracy for either the purine or pyrimidine bases occupying the third position in the triplet, the vertical axis for this position has been suitably condensed. '*X*' indicates codons thought to cause chain termination; '?' indicates uncertain assignments

nucleotide base to another are equally likely, it is possible to calculate the expected outcomes of random one- and two-step mutations. A single triplet can give rise to nine others by a one-step mutation and to eighty-one (including itself) by two-step changes. As in the previous communication[1], the amino-acid interchanges can be divided into three gross categories: (I) polar to polar or hydrophobic to hydrophobic; (II) between polar and glycine or alanine; (III) between polar and hydrophobic. While type I changes would appear to be favourable and type III unfavourable, those of type II could be either, depending on their location. A type II change affecting the surface would not be expected to be unfavourable; that affecting the interior of the molecule (and usually glycine or alanine→polar) would probably be unfavourable. The assignment of the amino-acids to the groups of polar and non-polar is also as before, and is based on the distribution of residues observed by Kendrew in myoglobin[4]. The frequency distribution of the various outcomes is shown in Table 1. It is soon apparent that, in nearly every case, type I mutations predominate over type III. Moreover, between 0·11 and 0·33 of the mutations would result in the same amino-acid and would not, therefore, be recognizable. If the frequencies are averaged over all amino-acids, weighting each triplet equally, the distributions shown at the bottom of Table 1 are obtained. If only observable mutations (mutations not leading to the same amino-acid) are counted and mutations leading to uncertain outcomes are eliminated, the results are I : II : III = 0·56 : 0·12 : 0·31 for one-step mutations and 0·52 : 0·14 : 0·34 for two-step mutations. Deriving distributions in this way may be misleading, since rare amino-acids are weighted as heavily as common ones. Therefore, frequencies have been calculated for a protein with the composition of the β-chain of human haemoglobin[14]. The results, which represent the expected observable outcomes of random nucleotide substitutions in the β-chain gene, are 0·62 : 0·14 : 0·25 and 0·53 : 0·16 : 0·32, for one- and two-step mutations, respectively. The weighted frequencies, which are not greatly different from those obtained without weighting, indicate that not more than one-quarter to one-third of observable random mutations will be of type III. These figures are considerably lower than the value of 0·40 for type III mutations obtained in the absence of information about the code and used in the previous analysis.

When such estimates of the outcomes of random mutations are applied to amino-acid substitutions found in actual proteins, certain difficulties immediately become apparent. Chief among these is knowing in which direction a given mutation has occurred. For example, if proline and glutamine (a type III combination) are found in homologous positions, the expectation of a type III outcome is either 0·67 or 0·29, depending on whether glutamine was substituted for proline or vice versa. Furthermore, the finding that two amino-acids are interconvertible by a single-step mutation does not ensure that one is derived from the other. Both may be derived from a third amino-acid. Likewise, amino-acids two mutational steps away from each other may both be derived, by single-step mutations, from a third common precursor. Therefore, in order to make meaningful estimates of how random a group of observed mutations may be, it is important to know the order in which such mutations have occurred. There are only a few instances in which such information is available, and two of these will now be examined.

More than thirty single-step mutations involving either the α-, β-, γ- or δ-chains of human haemoglobin or the evolution of the δ- from the β-chain are known and have been summarized by Beale and Lehmann[15]. If only those

Outcomes of one- and two-step mutations involving the codons for the various amino-acids. The proportions of recognizable mutations were calculated by eliminating all self, termination, and uncertain outcomes, and by assuming that all other triplets would actually code for their respective amino-acids.

cases in which the direction of mutation is known are considered (all the single-site changes and some of the β→δ substitutions), and if allowance is made for the fact that most of these mutations were recognized by differences in electrical charge (the *M* mutations, which are recognized in a special way, are omitted), the expected ratios of outcomes of observable random mutations is calculated to be I : II : III—20·8 : 5·6 : 4·7 (for a total of thirty-one mutations). The observed ratios are 20 : 10 : 1, and although there is a deficit of observed type III and an excess of type II changes (in this case, all involving surface residues) the small numbers would not allow the differences between the observed and expected ratios (considering I + II to be favourable, and III unfavourable) to be significant. It is conceivable, although probably not likely, that the results might ultimately be compatible with complete randomness of mutation. These mutations are relatively late in appearance and, except for rare cases such as haemoglobin S, have probably not yet been strongly selected for or against. Furthermore, in most instances a single non-permissible (type III) substitution, especially one involving a surface residue, would probably not seriously interfere with the proper folding of the molecule.

On the other hand, when two proteins which have evolved over a long period of time (such as the β- and γ-chains of haemoglobin) differ in more than a quarter of their residues, selective forces, if operative, should become apparent. If the evolutionary scheme proposed by Ingram[16] is accepted—with the α- and γ-chains having a common precursor, and the β-chain diverging from the γ later (that is, [α+β+γ] precursor→α-chain+[β+γ] precursor; [β+γ] precursor→β+γ-chains), it is possible to ascertain the direction of mutation during the divergence of the β- and γ-chains. Thus, if the α- and β-chains have a common amino-acid at a homologous location and the γ-chain a different one at the same site, the mutation can be considered as having occurred in the β→γ direction. Conversely, if α and γ have the common amino-acid, the mutation should have occurred in the γ→β direction. The β- and γ-chains differ at thirty-nine residues[14,17], and the direction of the mutation can be determined for twenty. Of these twenty mutations (sixteen of which involve exterior residues, four interior residues), the ratio of types I : II : III is 13 : 6 : 1; fourteen are one-step, four two-step, and two may be either one- or two-step depending on whether an uncertain set of codons for arginine (AGA, AGG) is allowed. The expected outcomes of random mutations involving the same group of starting amino-acids are in the ratio 10·9 : 4·7 : 4·4 (or 11·3 : 4·5 : 4·2 if the uncertain codons for arginine are used). There are fewer type III and more type I changes than expected, but the differences between observed and expected ratios could not, again, be significant because of small numbers. For the present, these results must be considered more in the nature of an illustration than as a definitive test of the code versus selection question. The latter will require the examination of a much larger number of mutations to allow for any valid conclusions. Nevertheless, the tendency in both sets of data is toward a deficiency of type III mutations. If the data are combined and the observed and expected ratios of I + II ('favourable') to III ('unfavourable') compared, the differences are statistically significant ($P < 0{\cdot}05$).

The limited data under consideration also provide some information about the kinds of mutations that have taken place. If each interchange is characterized in terms of the specific member of the triplet that has been altered, the results are as follows : for the haemoglobin single-site mutations and β–δ-chain conversions—first nucleotide base, 15; second, 14; third, 2; for haemoglobin β- and γ-chain comparisons—first, 13; second, 8; third, 4; first or third, 2. In both instances, the number of mutations involving the first or second base in a triplet are approximately equal. The numbers involving the third base are much lower. This is understandable, since, in general, a third of all third-place mutations would not be recognizable (for example, when U and C or A and G are interchanged). Furthermore, for half the triplets, none of the mutations at the third position would be recognized (for example, valine, alanine, proline) since the identity of these amino-acids is fully specified by the first two bases in the codon. As a result, no more than a third of the mutations at the third position in the triplet would be detected. For the single-site mutations, which depend principally on charge differences for detection, the expected ratios of detectable (by charge) changes involving the three nucleotide positions would be about 4 : 5 : 1. For the two groups of amino-acid exchanges under consideration, the observed ratios are close to what would be expected, and there does not seem to be any predilection for mutation in a specific position in the RNA codon.

Nucleotide base substitutions may be characterized as either transitions (pyrimine ↔ pyrimidine or purine ↔ purine) or transversions (pyrimidine ↔ purine). Theoretically, any nucleotide base may, by single-step mutations, undergo two transversions and one transition. However, of the three transitions available to a triplet, that involving the third base would not be detectable. Conversely, of six transversions which a triplet may undergo, the two involving the third base (or a third) would not be detectable in half the triplets (leucine, valine, alanine, etc.), or, in other words, a sixth of all transversions would not be detectable. Therefore, if mutations are random, the expected ratio of observed transitions to transversions should be approximately $(3 \times \frac{2}{3}) : (6 \times \frac{1}{6}) = 2 : 5$. Even if detection of mutants by charge differences has occurred, the ratio should be very similar. The ratios observed are 9 : 15 with two mutations indeterminate (or 11 : 11 if uncertain codons are assumed) for the haemoglobin β- and γ-chain comparisons, and 19 : 12 for the single-site mutants. There does appear, especially in the latter instance, to be an excess of transitions relative to transversions, although not of the degree suggested by Freese and Yoshida[18] on the basis of their work in bacteria. However, in line with the work of these authors, transitions from GC to AT pairs are favoured over the reverse direction, 20 versus 8. Further investigation of these points will be necessary since they will give an indication of the degree of randomness of the mutation process itself and may have to be taken into account in future calculations.

What, then, can be said about the initial question of the effect of the code versus natural selection in determining the sequences of proteins during the course of their evolution? It must first be realized that certain amino-acid substitutions, or at least substitutions at specific sites in the sequences of proteins, may not occur at all. This has been well documented by Margoliash and Smith[19] in the cytochrome c series in which many sites are invariant, that is, have apparently not been altered by mutation. Likewise, as has already been mentioned, the interiors of various globins virtually never contain polar residues, although several different hydrophobic groups may occupy the same position[6]. Presumably, these 'invulnerable' amino-acid residues are essential for specific aspects of the structure or activity of the protein, and their alteration would have grave consequences at a molecular level. For this group of residues, selection for conformation must clearly be present. Undoubtedly, there are also substitutions which, for reasons that may not be readily apparent, result in a distinct biological advantage or disadvantage to the host and will be strongly selected for or against. However, alterations of many of the residues of a protein during evolution probably do not have such gross effects, and it is with this group that we have been primarily concerned. On the basis of the studies of Perutz *et al.*[6], and of the analyses of properties of the code itself and two limited examples from the human haemo-

globins, it seems likely that we are observing a combination of two factors—natural selection, especially for amino-acid residues in the interiors of the proteins, superimposed on a high degree of conservatism (on a polarity basis) imposed by the amino-acid code itself. The conservatism inherent in the code may be sufficient to maintain the integrity of the surface residues which, as a group, are probably capable of greater variability than was initially appreciated. It must again be pointed out that if all mutations, rather than just those which are observable as changes in sequences, are considered, between one-sixth (for two-step changes) and one-quarter (for one-step changes) will not result in an amino-acid alteration—another element of conservatism inherent in the code.

Since the amino-acid code does favour mutations which would, in general, be expected to produce the least deleterious effects on structure and, since it is itself non-random in the assignment of codons, it is reasonable to enquire into the genesis of the code itself. Recent writers[11–13] on the subject have discussed two major possibilities—either there is a special chemical affinity between the amino-acids and the nucleotide bases in the so-called 'anticodons' (the triplet in the transfer RNA that is supposed to recognize the codon in the messenger RNA) or the code has itself evolved to its high degree of order by natural selection. Most authors appear to favour the former possibility, although there is not, at present, any chemical evidence to support it. Their hypothesis would require a specific inter-relationship between an amino-acid and the anti-codon part of its transfer RNA, a situation which cannot be examined until the tertiary structure of the transfer RNA molecule is known.

The simple evolution of the code to its present state has been rejected because of the seeming statistical impossibility of arriving at such an ordered set of triplets by natural selection alone[11,13]. Such an argument cannot be accepted, since it could be made to apply with equal force to virtually any set of complex processes or even morphological characteristics in which the role of evolution is unquestioned. Certain suppressor mutations (non-structural gene mutations which allow for the synthesis of proteins with mutations in their structural genes) have been thought to involve an alteration in the specificity of transfer-RNAs for specific amino-acids or codons[20]. It is easy to visualize that similar mutations could, over a long period of time, allow for the reshuffling of the codon assignments until a favourable set is obtained. As Sonneborn[21] has pointed out, the driving force for such assignments would be the minimization of the deleterious effects on organisms which would result from mutation. Preservation of the tertiary structure of proteins could act in such a way, and it may be suggested, therefore, that the codon assignments have been influenced, at least to a significant extent, by the need to ensure the proper folding of proteins.

Note added in proof. In a paper published after submission of this manuscript, Woese[22] has suggested that the code evolved to reduce translational errors (during protein synthesis) rather than mutational errors (during gene replication) as is proposed here. Also, a representation of the code analogous to that in Fig. 1 has recently appeared[23].

LEUCOCYTE ANTIGENS IN MAN: A COMPARISON OF LYMPHOCYTOTOXIC AND AGGLUTINATION ASSAYS FOR THEIR DETECTION

By JULIA BODMER and WALTER F. BODMER

Department of Genetics, Stanford University School of Medicine, Palo Alto, California

DR. ROSE PAYNE

Department of Medicine, Stanford University School of Medicine, Palo Alto, California

AND

PAUL I. TERASAKI and DONNA VREDEVOE

Department of Surgery, University of California, Los Angeles School of Medicine

THE need for *in vitro* histocompatibility tests for the matching of donors and recipients for transplantation is now generally appreciated. There is evidence to show that histocompatibility antigens occur on the leucocytes. This, together with the recent success in the establishment of human leucocyte isoantigenic groups, underlines the importance of using leucocytes for histocompatibility typing.

The first genetic polymorphisms involving leucocyte isoantigen systems in man were delineated by agglutination methods[1–3]. The question arises as to whether the same systems can also be detected by lymphocyte cytotoxic methods. Cytotoxicity assays have been used successfully in the identification of antigenic differences between leucocytes in mouse[4,5] and man[6,7]. Although no leucocyte antigen systems have as yet been identified in humans using the cytotoxicity assays, a comparison of these two methods has some practical interest.

As an initial approach, sera known to possess leuko-agglutinins produced by multiparous women were tested

for cytotoxic activity. A comparison of the frequency of reactions when tested on a panel of random donors was first made. Secondly, the sera shown by Payne *et al.*[2] to have LA1 and LA2 and 4a and 4b specificities were studied to determine whether they could be classified into the same groups when assayed for cytotoxic activity.

The agglutination tests were performed at Stanford University School of Medicine and tests for cytotoxic activity at the University of California School of Medicine at Los Angeles. The leucocyte agglutination test used by Payne has been described in *Methods in Medical Research*, 1964[8], and the lymphocyte cytotoxicity test has been described in detail by Terasaki and McClelland[9].

The first study involved twenty-four agglutinating antisera, including representatives of LA1, LA2, 4a and 4b types, some monospecific and some multispecific. The lymphocytes from seven members of a leucocyte donor panel, repeatedly typed by agglutination tests, were examined by the cytotoxicity assay. The antigen profile of the seven panel members had been well established with respect to some of the known systems, as well as the unclassified sera used in this study. A summary of the comparison between the two tests using this panel is shown in Table 1.

Table 1. COMPARISON OF THE AGGLUTINATION AND CYTOTOXICITY TESTS USING TWENTY-FOUR LEUCOCYTE ANTISERA WITH A SEVEN-MEMBER LEUCOCYTE PANEL

Agg.	Cyto.	No. of tests
+	+	61
+	−	17
−	+	0
−	−	68
		146
		$\chi^2 = 85{\cdot}3$

There is a reasonably high degree of agreement between the tests by the two methods. Out of a total of 168 comparisons there were seventeen (10 per cent) cases of a definite discrepancy between the two methods, all of which were agglutination positive – cytotoxicity negative. There were also twenty-two comparisons which could not be satisfactorily evaluated owing to conflicting results in one or the other method on repeated tests. Leaving out these latter comparisons, the χ^2 testing the association between the two methods is 85·3 for 1 d.f., which is highly significant. It seems worth noting that six of the definite discrepancies involved the monospecific 4b type sera, Nos. 13, 18 and 26, none of which gave a single positive result in the cytotoxicity test with this panel. There was no clear indication of a relation between discrepant results using the two assays and the reproducibility of a given serum based on the agglutination assay.

The next study consisted of a much more extensive series of cytotoxicity tests run with more than 200 lymphocyte donors using the same twenty-four antisera. The aim was to compare frequencies of reaction in the two methods and to see whether the cytotoxicity assay would detect two known leucocyte antigen systems, LA and group 4[1,2]. Table 2 compares the frequency of reaction by the two methods. Column 5 shows the difference between the percentage frequencies obtained by agglutination and cytotoxicity assays and Column 6 the χ^2 testing the significance of this difference. Agglutination frequency exceeded that obtained by cytotoxicity in all except two cases (sera No. 3 and No. 22). Nine of the antisera had a frequency difference which was less than 10 per cent, and not significant at the 5 per cent level. The remaining fifteen antisera all had frequencies more than 10 per cent lower by cytotoxicity than by agglutination, which differences were significant at least at a 5 per cent level. The nine sera which reacted with similar frequency in the two methods included a monospecific LA1, No. 14, a monospecific LA2, No. 28, and a 'limited' 4a serum No. 27. ('Limited' serum refers to one which reacts with some but not all 4a cells.) The high proportion of cases in which the cytotoxicity assay gives a significantly lower frequency of reaction than the agglutination assay, as shown in Table 2, suggests that it may be possible for sera to contain one, two or more agglutinating antibodies, none or not all of which have cytotoxic activity. This could be the situation, for example, in the case of serum No. 25 containing anti-LA1 and an anti-4b type antibody, the frequency of which by the cytotoxicity method (36 per cent) was considerably lower than that given by the agglutination method (65 per cent) and corresponds to the expected population frequency of LA1. It seems from these data that anti-LA1, and anti-LA2 and 4a type antibodies in most of these sera are detected satisfactorily by this cytotoxicity method whereas anti-4b type antibodies are not.

The results of a two-way analysis of these cytotoxicity data for purposes of grouping following Payne *et al.*[2] are shown in Table 3. The values in the body of the tables are the 2×2 χ^2 with an asterisk denoting a negative association. The top part of Table 3 relates to antisera detecting antigens of groups LA1 and LA2, and the

*LA*1	0·1786 ± 0 020	0·1617 ± 0·023
*LA*2	0·2355 ± 0·023	0·2811 ± 0·030
*LA*3	0·5859 ± 0·027	0·5572 ± 0·033

χ^2_1 testing goodness of fit of expected phenotype frequencies for the cytotoxicity is 7·51 ($P < 1$ per cent) of which 4 25 is due to excess of observed over expected LA1 + LA2 + cases.
* Data from Payne *et al.* (ref. 2).

bottom part to antisera detecting antigens of the 4 system. The LA1 antisera show significant positive associations with each other, indicating that they share a common antibody. Similarly, the LA2 antisera, with the exception of No. 6, show highly significant positive associations. As pointed out by Payne *et al.*[2], allelism of LA1 and LA2 would be indicated by a negative association between pairs of sera, one from each group. Fifteen out of the twenty associations between the LA1 and LA2 antisera are negative, although only two of these are significant at the 5 per cent level. Using the agglutination assay a larger proportion of the negative associations between the LA1 and LA2 sera were significant. This apparent discrepancy may be due to the inclusion of some familial data in this analysis. Familial data were specifically excluded from the agglutination data analysis. Thus it appears that the cytotoxicity assay identifies the LA1 and LA2 groups although the allelic relationship between them is not so clearly demonstrated. In the case of the 4a, 4b classification, the 4a antisera reacted well and there is a significant positive association between them. The 4b antisera, however, showed no significant positive associations and three of them (Nos. 10, 13 and 18), as already pointed out, reacted with significantly lower frequencies than are obtained with the agglutination assay (Table 2). So far as the allelic relationship between 4a and 4b is concerned, there is only one significant association between a 'limited' 4a antiserum, No. 33, and a 'limited' 4b, No. 26. There are no consistent significant associations in the data on cytotoxicity between the LA sera and the 4 sera, nor are there any consistent associations between these groups and the sera which do not fall into either of these systems.

Table 4 compares the population frequencies of the LA1 and LA2 types and derived *LA*1, *LA*2 and *LA*3 gene frequencies obtained in the present investigation by cytotoxicity with those reported by Payne *et al.*[2].

Neither population phenotype nor gene frequencies showed significant differences. However, for the cytotoxicity data, the observed frequency of *LA*1 and *LA*2 heterozygotes is significantly in excess of that expected on the basis of the estimated gene frequencies. This again, as has already been discussed, is probably due to the inclusion of some familial data. In spite of this discrepancy there is good correspondence between the *LA*1, *LA*2 and *LA*3 gene frequencies obtained from these two independent bodies of data.

Considering the data as a whole, good agreement between cytotoxicity and agglutination assays has been demonstrated. In approximately a third of the cases tested, sera reacted with comparable frequency in the two methods. These cytotoxicity assays thus detected many of the same leucocyte antigens identified by the agglutination assay. Where discrepancies exist, they are in the direction of more positive agglutination reactions. It is of interest to note that when two sera, No. 33 and No. 28, the agglutinating antibody of which had been completely absorbed out, were tested by cytotoxicity with cells which in a previous cytotoxicity test had been positive with the unabsorbed serum, no cytotoxic activity was found. This indicated that a quantity of cells sufficient to absorb all agglutinating antibody also removed all cytotoxic activity.

There are two basic differences between the tests, namely: (1) The agglutination test utilizes a cell suspension containing granulocytes and lymphocytes, whereas in the cytotoxicity test only lymphocytes are present. (2) The cytotoxicity assay depends on the ability of an antibody to fix added complement. For the sera tested here, it has been shown that the agglutinating activity can be absorbed out by lymphocytes, which indicates that the antigens that these sera detect are not specific for granulocytes[2]. The first point, therefore, cannot be a factor contributing to the lower frequency by cytotoxicity in these data. EDTA is not used in the agglutination assay and a small amount of complement is always present. Nevertheless, the existence of some non-complement binding antibodies in these sera may have been a factor leading to greater positive reactions by agglutination than cytotoxicity. Among the technical variables which could account for the differences are: (1) the sera for this study had been selected on the basis of their agglutinating ability, whereas sera selected by cytotoxicity were not investigated; (2) cytotoxicity was assayed with a maximum of 0·004 ml. of antisera, and use of larger volumes might have produced a higher percentage of positive results; (3) cytotoxic activity which declines on prolonged storage and heat inactivation may have deteriorated, whereas the agglutinating activity has not. The inactivation of all the sera tested here by heating at 56° C for 30 min may thus have affected the cytotoxic assay, particularly in those sera the cytotoxicity of which is weakest. Any assessment of the relative importance of the foregoing factors in the explanation of the differences observed will require considerable further work.

There is much evidence accumulating which favours the hypothesis that some of the leucocyte antigens may be important histocompatibility factors[10–14]. Preliminary investigations undertaken in an attempt to correlate survival of skin grafts with compatibility for the 4, 5 and 6 systems have given negative results[15,16]. The correlation between survival of kidney transplants of the Denver series and compatibility in the LA system as determined by the cytotoxicity assay is now being investigated. It is interesting to note that Simonsen[17] has suggested, on the basis of survival of kidney transplants and the frequency of graft-versus-host reactions in the lymphocyte transfer test, that if there is just one

major histo-compatibility locus in man, this may have only three alleles. Although the assumption of a single strong locus may be questioned, this calculation emphasizes the importance of correlating compatibility for each new leucocyte group by more than one assay with survival of homotransplants.

EFFECTS OF TOTAL-BODY X-IRRADIATION IN SINGLE AND FRACTIONATED DOSES ON DEVELOPING CEREBRAL CORTEX IN RAT FOETUS

By L. A. JACOBS and Prof. K. R. BRIZZEE*

Department of Anatomy and Division of Neurology, University of Utah College of Medicine and Departments of Obstetrics and Gynecology, Anatomy and Eppley Institute for Research in Cancer and Allied Diseases, University of Nebraska College of Medicine

INTEREST in dose fractionation procedures in radiological studies has arisen in part from a consideration of the clinical advantages to be gained through these procedures[1,2] as well as from an interest in the resilience or recovery ability of irradiated cells and tissues[3,4]. While there is considerable evidence indicating that a single exposure at a given dose-level results in more severe effects and/or a higher incidence of effects than do fractionated exposures producing the same cumulative dose[5–8], there is some evidence to the contrary[9–11]. It has become apparent that the end result of any given dose fractionation regimen depends on a number of variables. Among the more important of these are number of fractions, size of each fraction, intervals between fractions. total exposure time, dose-rate, changing sensitivities of cells throughout a given period of irradiation, degree of oxygenation of tissues and the time of exposure in relation to the various phases of the cell replication cycle.

One of the aims in the investigations we have recently initiated[12] on dose fractionation is to determine the relative importance of such variables on fractionated exposures in developing nervous tissues *in vivo*. This article reports results of preliminary investigations of histological effects of single and fractionated doses of whole-body X-irradiation in developing cerebral cortex in the foetal rat.

The foetuses used in this study were taken from Sprague–Dawley female rats the pregnancies of which were timed. Three series of animals were collected, namely, control, 150 r. single exposure and 150 r. fractionated exposure. The single exposure was given at 50 r./min for 3 min and the fractionated exposures were given at 50 r./min in individual 1-min doses at 9-h intervals. The morning of the sperm-positive determinations was considered day zero. Irradiation was initiated on gestation day 13 at 10 a.m. The foetuses were taken at 24-h intervals thereafter. A minimum of four foetuses was used for study of each foetal day for each treatment.

The irradiation was given by placing the females in a snug-fitting 'Lucite' box allowing dorsal exposure. The dose was determined by means of a Victoreen dosimeter with the probe placed inside a paraffin block within the 'Lucite' box. Irradiation was administered with a Westinghouse 'Quandrocondex' unit operated at 250 kVp. at 15 m.amp with a filtration factor of 1/2 mm copper and 1 mm aluminium.

* Present address: Division of Neurology and Department of Anatomy, University of Utah College of Medicine, Salt Lake City.

On the proper gestation day each rat was anaesthetized with sodium pentobarbital and the foetuses removed by Caesarian section. The calvaria were removed and the brains fixed by immersion in Bouin's solution, embedded in paraffin, sectioned at 10μ, mounted and stained with iron haematoxylin and acid fuchsin. The region of the brain studied in the foetuses corresponds to area 2 as described by Kreig[13] for the adult rat brain. The following descriptions apply only to this area except where otherwise noted.

The 14-day control animals present a ventricular wall with a dark-staining ependyma and a lighter-staining mantle layer, which generally extends dorsally only as far as the apex of the hemisphere, having a solitary ependymal layer extending down the medial wall. The cells in the ependymal layer are arranged in longitudinal rows or columns extending from the inner (luminal) border of the hemisphere wall outward toward the mantle layer. A single row of mitotic figures characterizes the inner row of ependymal cells, while other scattered mitotic figures are seen in the remainder of the ependyma and the mantle layer.

In the 14-day-old single-dose animals the luminal wall of the hemisphere is highly irregular in contour, and the mantle layer is seen only in the low lateral area. The ependyma has been severely disrupted and in many sites is not recognizable as a distinct layer. Rosettes are clearly seen throughout the hemisphere, and large evaginations of the ventricular wall protrude into the ventricle. Numerous sloughed pyknotic nuclei are observed within the cavity, and large macrophages are commonly seen in this cellular debris with whole and fragmented nuclei within their cytoplasm.

Both the cells forming the rosettes and the surrounding cells have staining characteristics that resemble normal ependyma. Many pyknotic nuclei interspersed with cells exhibiting mitotic nuclei are found in both the ependyma and mantle layer, and mitotic figures are also numerous in the rosettes.

In the brains from 14-day-old foetuses which received the fractionated dose, the luminal wall is generally intact, and there are no sloughed neural elements or phagocytic cells in the ventricles. The wall of the hemisphere is smooth without gross deformities and is thicker than the wall in 14-day-old control animals. The ependymal layer is distinct, although its outer margin often has a frayed or indefinite appearance, and the mantle

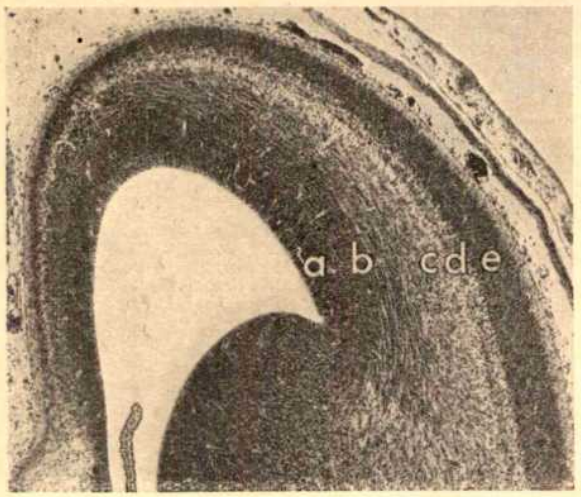

Fig. 1. Transverse section of cerebral hemisphere of normal 17-day-old foetus. Stained with haematoxylin and acid fuchsin (× 45). (*a*) Ependymal layer. (*b*) Subependymal zone of mantle layer. (*c*) Intermediate zone of mantle layer. (*d*) Secondary migratory lamination. (*e*) Primordial cortical layer

layer extends over the dorsal wall and down the medial wall. Mitotic cells are numerous in the ependymal and mantle layers, and a large number of pyknotic cells are seen in the mantle layer. These cells appear to be as numerous as in the single-dose series. It is particularly noteworthy that no rosettes are seen in these brains.

In the 17-day-old control animals, the mantle layer has taken on a somewhat striated appearance (Fig. 1) with the cells oriented in laminae more or less parallel to the pial surface and running ventrically toward the corpus striatum. Within the mantle layer two well-defined zones may be distinguished: an inner sub-ependymal zone (Fig. 1*b*) and an outer intermediate zone (Fig. 1*c*). The latter is characterized by a thinning out of cells (decreased cell packing density) as compared with the other layers at this stage of development.

The primordial cortical layer (Fig. 1*e*) which forms the primary migratory lamination[14] in the lateral wall on the fifteenth day of gestation (sixteenth day of Tilney[14]) now constitutes a very definite layer many cells in thickness extending over the roof and down the medial walls. There is also evidence of a secondary migratory lamination (Fig. 1*d*) which, in our preparations, is first seen at 16 days. This layer is observed to extend as far as the dorsal wall at this stage. The mean value for depth of the primordial cortical layer is about 150μ in these preparations, while depth of ependymal and mantle layers combined is approximately 400μ.

The brains from 17-day-old animals which received a single exposure appear to be markedly retarded in development (Fig. 2), and rosettes are still evident in dorsal and lateral walls. The primordial cerebral cortex (Fig. 2*c*) has not reached the medial wall but is evident on the lateral and dorsal walls. No evidence of a secondary migratory lamination beneath the primordial cortical layer is seen. The ependyma and sub-ependymal layers (Fig. 2*a*) are not easily differentiated but can be clearly distinguished from the primordial cortex, which appears more distinct and uniform and measures about 70μ in depth. The combined ependymal and mantle layers measure about 265μ in these animals.

In the 17-day-old foetuses which received the fractionated dose the ependyma and sub-ependyma are similar to the controls (Fig. 3), but the primordial cortical layer (Fig. 3*e*) is not so well developed and is poorly distinguished on the medial wall. Some evidence of a secondary migratory lamination is seen in the lower lateral wall (Fig. 3*d*) extending nearly to the apex. The primordial cortex is about 120μ in depth and the combined ependymal and mantle layers measure approximately 412μ.

The brains from 20-day-old control animals exhibit a relatively deep cortical layer blending indefinitely into the mantle layer, with the cells still oriented in vertical columns perpendicular to the plane of the pial surface. The distinction between the ependymal and sub-ependymal tissues and the intermediate zone is now quite apparent. The latter zone exhibits decreased cellularity as compared with earlier stages, but some strands of cells parallel to the cortical layer, apparently constituting part of the secondary migratory lamination, are seen deep to the cortical layer. At this stage of development the cortical layer is about 330μ in depth while the combined ependymal and mantle layers measure 570μ.

In the 20-day-old single-dose animals the lateral ventricles are clear but the luminal wall remains irregular. The ependymal and sub-ependymal areas are not well defined and the cells and their processes are arranged in a random pattern, appearing to be more widely spaced than in controls. The rosettes are still numerous but have lost their clear spherical centre and radiating character and

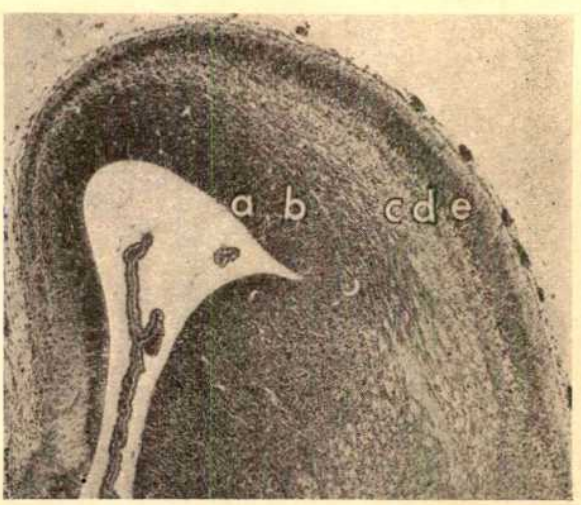

Fig. 3. Transverse section of cerebral hemisphere of 17-day-old foetus given fractionated dose of 150 r. on thirteenth gestation day. Stained with haematoxylin and acid fuchsin (× 45). (*a*) Ependymal layer. (*b*) Subependymal zone of mantle layer. (*c*) Intermediate zone of mantle layer. (*d*) Secondary migratory lamination. (*e*) Primordial cortical layer

now appear as a mass of densely packed, dark-staining, unorganized tissue. The primordial cerebral cortex is present and extends to the medial wall, but it appears that the secondary migratory lamination has not yet formed. The ependymal, sub-ependymal and mantle layers all appear very disorganized and exhibit numerous whorls of fibres and masses of interdigitating fibres. The cortical depth in these brains averages 230μ and the ependymal and mantle layers combined measure about 640μ in thickness.

The brains of 20-day-old fractionated dose animals resemble the brains of the controls with the exception that they are much smaller and the primordial cortex is thinner. The latter measures about 270μ, but the combined depth of the ependymal and mantle layers is about equal to that in the control brains.

In summary, the results observed in this preliminary histological study are in general agreement with the findings of many workers involved in dose fractionation studies[5–8] in that more severe effects are observed with the single exposure than with fractionated doses. Whether the differences between single and fractional exposures may be explained entirely on the basis of cell recovery between fractions[3,4] or partly by other factors (for example, a relatively smaller effect or a disproportional inefficiency of the individual fractions[7]) cannot be determined from the data at present available.

This investigation was supported in part by an Atomic Energy Commission contract, a research grant from the National Institute of Neurological Diseases and Blindness and a University of Nebraska American Cancer Society Institutional grant.

EFFECT OF AGENTS SIMULATING THE ABNORMALITIES OF THE GLUCOSE-6-PHOSPHATE DEHYDROGENASE-DEFICIENT RED CELL ON *Plasmodium berghei* MALARIA

By Dr. SIMEON POLLACK, Captain JAMES N. GEORGE and Colonel WILLIAM H. CROSBY
Department of Hematology, Walter Reed Army Institute of Research, Washington, D.C.

INDIVIDUALS whose red cells are deficient in the enzyme glucose-6-phosphate dehydrogenase (G6PD) appear to be more resistant to infection with *Plasmodium falciparum* malaria[1,2]. Associated with the deficiency of G6PD in red cells are (1) a relatively inefficient apparatus for reducing methaemoglobin[3] and (2) a relative paucity of reduced glutathione (GSH)[4]. It seemed possible that one or other of these could be responsible for rendering the G6PD-deficient red cell less suitable for the plasmodium.

If methaemoglobin accumulation or GSH deficiency were responsible for inhibiting growth of the malaria parasites, then agents which cause these abnormalities might alter the course of malaria infection. Sodium nitrite, a methaemoglobin producing agent[5], and alloxan and phenylhydrazine hydrochloride (PH), which have been shown to deplete red cells of GSH[6–9], were therefore tested in *Plasmodium berghei* infection.

The mice used were a Walter Reed derivative of the Bagg Swiss mouse, weighing 15–25 g. They were infected with varying doses of parasitized red blood cells by intraperitoneal injection.

The effect of therapy on survival of the treated and untreated animals was compared using the Mann-Whitney test[10], which compares medians and does not depend on a normal distribution for its validity. Preliminary investigation had indicated that the distribution of deaths in infected mice was not normal, for there was considerable skew to the right in the graph of mortality against time.

The percentage of parasitized red blood cells was determined on thin smears stained with Leishman's stain and counter-stained with Giemsa's stain[11]. Methaemoglobin was determined by the method of Evelyn and Malloy[12]. Red cell GSH was determined by the 5-5′ dithiobis (2-nitrobenzoic acid) method of Beutler *et al.*[13]. Reticulocyte counts were performed using brilliant cresyl blue[14]. The *P. berghei*, obtained from the laboratory of Dr. R. Coatney of the National Institutes of Health, was a derivative of the *NYU*–2 strain. Saline solutions of PH and alloxan were made immediately prior to use because of their instability[7,15].

A single dose of 3 mg sodium nitrite produced a moderate methaemoglobinaemia for 2–3 h. Twice-daily doses of 3 mg of sodium nitrite for seven consecutive days had no cumulative effect on the methaemoglobinaemia, was not lethal to mice, and failed to prolong survival (Table 1).

The effect of various daily intraperitoneal doses of PH is shown in Table 2. Small doses of PH significantly prolonged survival. The effect of a single dose of 2 mg of PH on the parasitaemia of infected mice is shown in Fig. 1: the developing parasitaemia was retarded for 3

Table 1. Effect of Sodium Nitrite on *P. berghei* in the Mouse

	Median day death	Day of death range
Control (9)*	10	(9–22)
Treated (9)*	8	(8–9)

Control and treated mice were infected with 10^5 parasitized red blood cells. 24 h after infection a single dose of 4 mg sodium nitrite was given by intraperitoneal injection to the treated group. Because this dose of sodium nitrite was lethal to one mouse, subsequent doses were 3 mg each. The mouse killed with sodium nitrite was excluded from the experiment. Methaemoglobinaemia reached a peak of 50 per cent between 60 and 90 min after injection of sodium nitrite; 3 h after sodium nitrite methaemoglobinaemia was less than 2 per cent.

* The numbers in parentheses are the numbers of animals in each group.

Table 2. Effect of Phenylhydrazine Hydrochloride on *P. berghei* in the Mouse

		Median day death	Day of death range	*P*
Untreated	(10)	8·5	(7–14)	
0·1 mg	(10)	15·5	(13–18)	< 0·002
0·5 mg	(8)	12	(10–17)	< 0·002
1·0 mg	(10)	14	(7–16)	< 0·002
1·5 mg	(9)	7	(7–12)	
Saline	(10)	8	(7–10)	

Mice were infected with 10^8 parasitized red cells. Phenylhydrazine hydrochloride in the indicated dose was given daily by intraperitoneal injection beginning on the day after the infection.

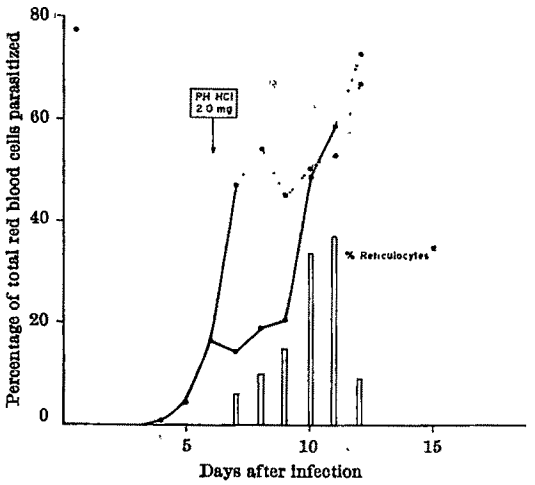

Fig. 1. Parasitaemia of *P. berghei* infected mice; response to a single dose of phenylhydrazine hydrochloride. Ten mice were infected with 10^5 parasitized red blood cells. 6 days after infection they were randomized into two groups. The treated group was given 2 mg phenylhydrazine hydrochloride by intraperitoneal injection. The control group was given an equal volume (0·2 ml.) of normal saline. The mean parasite count of each group is plotted. The broken line is used where the first mouse in a group has died. Parasitaemia was suppressed in the treated group for 3 days (lower of the two solid lines). The reticulocytosis resulting from a 2 mg dose of phenylhydrazine hydrochloride to a group of normal mice is shown in the bar graph*

days. The action of PH in retarding the development of parasitaemia and in prolonging survival of infected mice occurred despite the haemolysis and reticulocytosis that the drug produces. *P. berghei* infects reticulocytes preferentially, and animals treated to produce reticulocytosis ordinarily have an accelerated course with *P. berghei* infection[16].

One possible explanation of the antimalarial action of PH, which damages older red blood cells preferentially and leads to their selective sequestration in the spleen[17], is that it has the same effect on parasitized red blood cells. If PH were antimalarial solely by virtue of preferential sequestration of parasitized red blood cells in the spleen, then splenectomy would presumably obliterate its therapeutic effect. But PH exerted a significant therapeutic effect despite splenectomy (Table 3).

Table 3. INFLUENCE OF SPLENECTOMY ON THE EFFECT OF PHENYLHYDRAZINE HYDROCHLORIDE

		Median day death	Day of death range	P
Control	(9)	9·5	(8–15)	<0·02
Splenectomized +PH	(10)	14	(13–17)	

Splenectomy was performed one day before infecting mice with 10^5 parasitized red blood cells. A daily dose of 0·1 mg phenylhydrazine hydrochloride was given by intraperitoneal injection beginning on the day after the mice were infected. Control mice received 10^5 parasitized red blood cells only.

Table 4. EFFECT OF ALLOXAN ON *P. berghei* IN THE MOUSE

		Median day death	Day of death range	P
Control	(12)	10	(9–26)	<0·002
Alloxan-treated	(10)	19·5	(18–23)	

Mice were infected with 10^5 parasitized red blood cells. 3 mg of alloxan was given daily by intraperitoneal injection beginning on the day after the mice were infected.

Alloxan was tried next. Three mg of alloxan daily had a highly significant effect in prolonging survival (Table 4). Larger doses of alloxan proved too toxic for daily administration. The effect of a single dose of alloxan on parasitaemia is shown in Fig. 2. This dose of alloxan retarded developing parasitaemia for about a week; no anaemia or reticulocytosis resulted from this dose in normal mice.

Alloxan and PH had unmistakable antimalarial action against *P. berghei*, but their effect on red cell GSH in the normal, uninfected mouse was minimal (Table 5).

Table 5. RED CELL GLUTHATHION IN ALLOXAN- AND PHENYLHYDRAZINE HYDROCHLORIDE-TREATED MICE

		GSH		SD
Control*	(10)	65·1	±	4·8
Alloxan—2 h	(8)	67·8	±	7·3
Alloxan—6 h	(10)	69·5	±	6·6
Control	(8)	70·7	±	6·1
Phenylhydrazine 30 min	(9)	52 0	±	9·4
Phenylhydrazine 2 h	(9)	70·6	±	9·4

* Mice were randomized into three groups. The alloxan-treated mice received 7·5 mg alloxan by intraperitoneal injection and were killed 2 h and 6 h later.

† Mice were randomized into three groups. The treated mice were given 2 mg phenylhydrazine hydrochloride by intraperitoneal injection and killed 30 min and 2 h later.

Mice with parasitaemias of varying severity were also dosed with PH and alloxan and the GSH in their red blood cells determined; no consistent difference from the response of the normal mice to these agents was demonstrable.

Any discussion of the mechanism of action of these drugs is necessarily speculative. GSH depletion does not suffice as an explanation of their anti-malarial effect. Alloxan and PH have both been shown capable of inhibiting or destroying a variety of biological systems[21–29]. One property they share is the capacity to function as redox intermediates, causing the oxidation of substrates which ordinarily are not in ready equilibrium with oxygen. The action of PH in oxidizing haemoglobin is one example of this[30]; that of alloxan and dialuric acid in accelerating oxygen uptake in tissue homogenates is another[31].

The G6PD-deficient red cell is uniquely sensitive to oxidative haemolytic agents and is readily destroyed by them. It may be considered a 'defective' cell in this sense. The *Plasmodium* is also a 'defective' cell in the sense that it is an obligate intracellular parasite and therefore lacks at least one system essential to extracellular survival.

The susceptibility of both the *Plasmodium* and the G6PD-deficient cell to oxidative agents suggests that their metabolic defects may be similar. The relative insusceptibility of the G6PD-deficient red cell to *P. falciparum* is consistent with this hypothesis: the plasmodium does not prosper in the G6PD-deficient red blood cell because it needs what the host red blood cell possesses only in short supply. Tracer studies of plasmodial metabolism are consistent with this hypothesis: free *P. berghei* produced almost no $^{14}CO_2$ from ^{14}C-glucose labelled in the '1' position[32], suggesting that the pentose phosphate shunt in the parasite is either absent or incomplete.

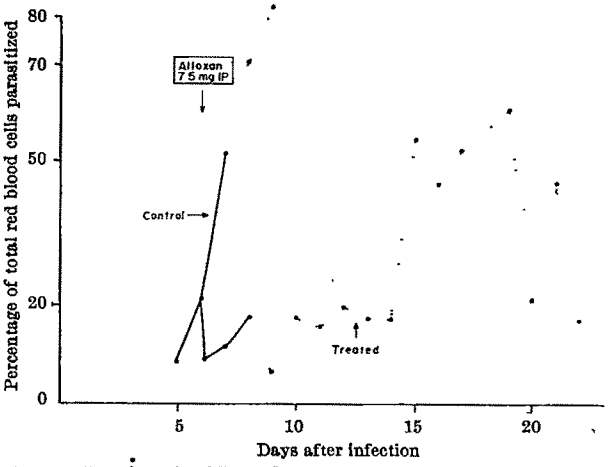

Fig 2. Parasitaemia of *P. berghei* infected mice; response to single dose of alloxan. Ten mice were infected with 10^5 parasitized red blood cells. 6 days after infection they were randomized into two groups. The treated group was given 7·5 mg alloxan by intraperitoneal injection. The mean parasite count of each group is plotted. The broken line is used after the first mouse in a group has died. Parasitaemia is suppressed in the treated group for 9 days. The early deaths in the treated group are attributable to alloxan toxicity. Median day death alloxan-treated mice: 21. Median day death control mice: 10

Finally, G6PD was not detected in the free parasites of *P. knowlesi*[33]. The consequence of a defect in the pentose phosphate pathway would extend beyond energy metabolism; a paucity of TPNH and of pentose sugars would affect lipid synthesis and nucleic acid synthesis. Separately or together, these could potently inhibit parasite growth and multiplication.

An antiplasmodial action of PH has also been noted by Ridgon[18]. An antimalarial effect of alloxan is apparent in the data of Tolbert[20].

Extrapolation of results with *P. berghei* to the metabolism or host–parasite relationships of *P. falciparum* is unwarranted. These studies are, at best, only suggestive of the state of affairs in human infections.

INCORPORATION OF CARBOXYL GROUPS INTO MELANIN BY SKIN TYROSINASE

By YU MIN CHEN and PROF. WALTER CHAVIN

Department of Biology, Wayne State University, Detroit, Michigan

IN the classic Raper–Mason[1] metabolic pathway of melanogenesis, the enzymatic conversion of tyrosine into melanin is accompanied by the cyclization and decarboxylation of intermediates. However, a series of recent investigations have indicated that carboxyl groups may be present in melanin derived from various sources. Magnesium and calcium salts of the carboxyl group are present in sepiomelanin[2]. Further, in sepiomelanin and in certain synthetic melanins, Piatelli *et al.*[3] have reported the presence of indole units with a carboxyl group at position 2 and pyrrolic acid units. Rat melanoma and human melanins also contain carboxyl groups, but in contrast to sepiomelanin, the mammalian pigment contains units of uncyclized carboxylated intermediates in the polymer[4]. Using carbon-14 carboxyl-labelled tyrosine and dihydroxyphenylalanine (DOPA) in the investigation of melanin formation by mushroom tyrosinase, the incorporation of the carboxyl group was obtained[5]. In experiments using 2-(3,4-dihydroxyphenyl)-ethylamine-^{14}C, with the label at various side-chain or ring positions, Swan and Wright[6] found that the oxidative fission of the indole intermediate into pyrrolic acid takes place during melanogenesis. Therefore, the carboxyl group in the melanin polymer may be derived from the breakdown of the indole benzonoid ring. However, Swan[7], with the aid of α- and β-deuterated 3,4-dihydroxyphenethylamine and 3,4-dihydroxyphenylalanine, showed the retention of deuterium in melanin formed either enzymatically or autoxidatively from the former substrate or autoxidatively from the latter substrate. Thus the substrates or their intermediates, without cyclization and decarboxylation, may be incorporated into the pigment. It is possible, therefore, that carboxyl incorporation may occur during melanogenesis under natural conditions. In the present article, the *in vitro* incorporation of the tyrosine or DOPA carboxyl group into melanin by fish skin tyrosinase is demonstrated.

Eight sexually inactive black moor goldfish (*Carassius auratus* L.), 3·79 ± 0·18 g in weight, were utilized in this investigation. The animals were maintained under constant conditions of temperature (25° C), photoperiod (12 h) and diet. All animals were acclimatized to laboratory conditions for a period of not less than 3 weeks prior to use. The fish were individually captured, immediately decapitated and the body skin with scales and fins removed without delay. The skin was immediately placed in a tared chilled beaker, weighed, and frozen (−27° C) for at least 5 h. The substrates used were L-tyrosine-1-^{14}C, DL-tyrosine-2-^{14}C, uniformly labelled L-tyrosine-^{14}C, DL-DOPA-1-^{14}C and DL-DOPA-2-^{14}C. The specific activities utilized are indicated in the appropriate tables. The details of the preparative procedures and assay method have previously been described[8]. All assays and controls were performed in duplicate.

In a comparison of uniformly labelled L-tyrosine with L-tyrosine-1-^{14}C, the DOPA-dependent incorporation of the carboxyl group of tyrosine into melanin is demonstrated. This is shown in Table 1. It is reasonable, therefore, to consider the incorporation of the carboxyl group into melanin as part of the action of tyrosinase.

Considering both carboxyl incorporation and decarboxylation, a correction factor for tyrosinase activity assayed with uniformly labelled L-tyrosine is necessary. This has been evaluated in the comparison of uniformly labelled L-tyrosine-^{14}C and DL-tyrosine-2-^{14}C as substrates assuming that D-form is not utilized (Table 2). With

Table 1. COMPARISON OF TYROSINASE ACTIVITY OF SKIN HOMOGENATES UTILIZING L-TYROSINE-1-^{14}C AND UNIFORMLY LABELLED L-TYROSINE-^{14}C AS SUBSTRATES. SPECIFIC ACTIVITY OF EITHER SUBSTRATE: 0·329 MC./MMOLE. MEAN ACTIVITY OF ASSAY EXPRESSED IN C.P.M.

3	—	—	4	40	—	164

* Specific activity of labelled substrates: 0 329 mc./mmole. Specific activity of L-form in DL-DOPA-2-^{14}C and DL-DOPA-1-^{14}C. 0·165 mc./mmole.

uniformly labelled L-tyrosine, an average loss of 9·28 per cent of the activity is incurred. However, with complete decarboxylation, one labelled carbon of the nine present in a molecule of uniformly labelled L-tyrosine should be lost. The difference between such theoretical loss (11·11 per cent) and the actual loss (9·28 per cent) is 1·83 per cent. The increase in radioactivity is produced by the incorporation of the carboxyl group of the substrate into the end-product. The radioactivity obtained with uniformly labelled L-tyrosine is 90·72 per cent of the radioactivity obtained with L-tyrosine-2-^{14}C. Therefore, the tyrosine activity assayed with uniformly labelled L-tyrosine can be corrected to the L-tyrosine-2-^{14}C value. Using such corrected uniformly labelled L-tyrosine values, the mean incorporation of radio-tyrosine without decarboxylation is no longer 10·46 per cent (Table 1) but 9·50 per cent. The incorporation of radio-tyrosine without decarboxylation can be determined directly by comparing L-tyrosine-1-^{14}C and DL-tyrosine-2-^{14}C as substrates, assuming that the D-form is not utilized. In both Tables 1 and 2, enzyme preparation 3 was the same. This calculated value is 10·51 per cent, which approximates to the calculated mean value, 9·50 per cent.

Although the incorporation of tyrosine without decarboxylation is the same for all three types of labelled tyrosine utilized, the radioactivity due to the incorporation of the carboxyl group is quite different. The gains in radioactivity are 0 per cent, 9·50 per cent and 1·06 per cent (1/9 × 9·50 per cent) using L-tyrosine-2-^{14}C, L-tyrosine-1-^{14}C and uniformly labelled L-tyrosine-^{14}C, respectively. The increased radioactivity due to the incomplete decarboxylation of uniformly labelled L-tyrosine should be equal to the increased radioactivity due to the incorporation of carboxyl group. The difference between 1·83 per cent and 1·06 per cent is probably due to experimental error. In any case, as the increase in radioactivity resulting from the incorporation of the carboxyl group of uniformly labelled L-tyrosine is small, it may be considered negligible. Thus, the results of the assay utilizing uniformly labelled L-tyrosine-^{14}C may be corrected for the radiocarboxyl loss by simply dividing by 90 per cent or multiplying by 1·11.

The incorporation of the carboxyl group of DOPA into melanin was also demonstrated (see Table 3). In a previous communication[8], 4 μg DL-DOPA (2 μg L-DOPA)/ml. incubation mixture has been found to be the saturated substrate level for tyrosinase, and has been utilized both as catalyst and substrate in the assay. Thus, this quantity of labelled DOPA was used as the substrate in the presence of unlabelled tyrosine. However, the tyrosinase activity obtained with DL-DOPA must be multiplied by 2, as the specific activity of the L-form in DL-DOPA is only half of that of the L-tyrosine used. Comparing DL-DOPA-1-^{14}C and DL-DOPA-2-^{14}C (Table 3), the incorporation of DOPA without decarboxylation into melanin is 28·65 per cent. The total activity obtained with DL-DOPA-2-^{14}C and uniformly labelled L-tyrosine-^{14}C was the same. Thus, the enzymatic rate of DOPA oxidation is about twice that of tyrosine and the incorporation of the DOPA carboxyl group is about three times that of tyrosine. Moreover, only the incorporation of radioactive tyrosine, but not unlabelled DOPA, into melanin is visualized when tyrosine alone is labelled. Conversely, the incorporation of radioactive DOPA but not unlabelled tyrosine into melanin is measured when DOPA alone is labelled. Therefore, the overall activity in c.p.m. using 40 μg L-tyrosine and 2 μg L-DOPA should be (166) (1·11) + (163) (2) = 508, which is about three times that of uniformly labelled L-tyrosine. This has been demonstrated previously[8]. In reality, the incorporation of tyrosine and DOPA without decarboxylation is neither 9·50 per cent (radioactive tyrosine) nor 28·65 per cent (radioactive DOPA) but 22·31 per cent, as obtained by the following calculation (Table 3):

Tyrosinase activity with uniformly labelled L-tyrosine:	163 c.p.m.
Tyrosinase activity with DL-DOPA-1-^{14}C:	48 c.p.m.
Tyrosinase activity with DL-DOPA-2-^{14}C:	164 c.p.m.
Tyrosinase activity estimated as L-DOPA-1-^{14}C:	(48) (2) c.p.m.
Tyrosinase activity estimated as L-DOPA-2-^{14}C:	(164) (2) c.p.m.

Using the correction factor 1·11 for utilizing uniformly labelled L-tyrosine-^{14}C and the estimated incorporation of tyrosine without decarboxylation, 9·50 per cent from Tables 1 and 2, the incorporation of tyrosine and DOPA without decarboxylation under the system investigated will be:

$$\frac{(163)\,(1{\cdot}11)\,(0{\cdot}095) + (48)\,(2)}{(163)\,(1{\cdot}11) + (164)\,(2)} \times 100 = 22{\cdot}31 \text{ per cent}$$

Carboxyl incorporation does not appear to result from the attraction between the carboxyl group of DOPA or tyrosine and the basic ring nitrogen of melanin, as little or no incorporation of other 14-labelled aliphatic amino-acids into the end-product was observed[8]. However, it is possible that DOPA, tyrosine or their metabolites with a carboxyl group may be attracted by melanin or a precursor by way of the carboxyl and phenol groups due to structural similarity and polarity. This may support the attraction hypothesis[8].

Melanin is formed by polymerization of indole-5,6-quinone, a metabolite from tyrosine or DOPA, by repeated oxidative condensation involving the anionoid centre of the pyrrole ring of one molecule and the cationoid centre of the benzonoid part of another[9,10]. The indole-5,6-quinone-2-carboxylic acid may be co-polymerized with

indole-5,6-quinone in acid solution although it is not oxidizable itself into melanin. In addition, direct incorporation of other potentially anionoid substances such as tyrosine or DOPA may also be expected during generation of the indole-5,6-quinone. Considering the basic principle of polymerization analogous to indole–quinone condensation, incorporation of the carboxyl group of tyrosine or DOPA into the melanin polymer[1–5,7] may result from copolymerization of these substances and their intermediates with melanin or precursors prior to decarboxylation. However, the carboxyl groups of the pyrrolic acid units in the melanin polymer originate from the breakdown of the indole benzonoid ring of the polymer[6], and thus are not derived from the carboxyl groups of tyrosine and DOPA.

In melanin formation, the incorporation of radio-DOPA without decarboxylation is much higher than that of radio-tyrosine without decarboxylation. The attraction hypothesis may explain this difference. As the degree of tyrosine or DOPA incorporation into melanin, using fish skin homogenates, is small[8], the amount of radio-DOPA and intermediates present at any time during incubation is also small. The effective concentration of radio-DOPA and intermediates will be much higher at any given time in a system of 40 μg L-tyrosine and 2 μg L-DOPA-^{14}C than in one with 40 μg L-tyrosine-^{14}C and 2 μg L-DOPA. At the beginning of incubation, the effective concentration of L-DOPA-^{14}C is 2 μg/ml. in the former system while it is zero in the latter system. During incubation, the probability that the concentration of radio-DOPA in the latter system does not attain the level present in the former is high for several reasons. The radioactive DOPA concentration in the latter system is reduced by the slow conversion rate of tyrosine to DOPA and, perhaps, partial loss of monophenolase activity in the enzyme preparation[11–13]. The polarity and structure of DOPA is more like that of the diphenolic compounds (or their quinone form) than tyrosine. Therefore, DOPA and its melanogenic intermediates may be more easily copolymerized than tyrosine. An intermediate which may be readily copolymerized is indole-5,6-quinone-2-carboxylic acid, which has been demonstrated in sepiomelanin[2–4]. Since the effective concentration of radio-DOPA is higher in a system utilizing labelled DOPA rather than labelled tyrosine the incorporation of the label by copolymerization will be proportionally higher in the former system.

From the foregoing discussion together with other available information[1–5,7–13], the following conclusions may be reached: (1) Only DOPA or its intermediates may readily be converted into a melanin precursor (indole-5,6-quinone) for polymerization. (2) Only DOPA or its intermediates may easily be attracted by melanin or a melanin precursor for copolymerization. (3) With the catalytic reaction of DOPA in tyrosine–DOPA conversion, enzymatically and/or autoxidatively the incorporation of tyrosine into melanin by polymerization and copolymerization may take place. (4) The direct incorporation of tyrosine into melanin with indole-5,6-quinone or into melanin by copolymerization is not excluded. (5) Both polymerization and copolymerization may be considered, primarily, to result from the attraction of the intermediates during melanogenesis.

Electron spin resonance studies have demonstrated the irregularity of the melanin polymer[14] as first suggested by Swan[7]. A portion of this irregularity may result from copolymerization. Further, during polymerization, cross-linkage may also be responsible for the irregularity[1,7,14] and this may also be produced by attraction at different sites of the same monomer. Thus, the attraction hypothesis may explain the observed irregularity of the melanin molecule by both polymerization and copolymerization. Under these circumstances, it is obvious that the molecular environment in the cell will directly affect the structure of the melanin polymer during melanogenesis. As the intra-cellular environment is in constant flux, the melanogenic end-product will also vary.

In summary. with the use of carboxyl-labelled tyrosine and DOPA, the incorporation of tyrosine and DOPA without decarboxylation into melanin by skin homogenates of black moor goldfish has been demonstrated. Comparison of the results obtained with L-tyrosine-1-^{14}C, DL-tyrosine-2-^{14}C, uniformly labelled L-tyrosine-^{14}C, DL-DOPA-1-^{14}C and DL-DOPA-2-^{14}C, the incorporation of radio-tyrosine without decarboxylation into melanin in the presence of unlabelled DOPA was 9·50 per cent of the total radio-tyrosine converted; the incorporation of radio-DOPA without decarboxylation into melanin in the presence of unlabelled tyrosine was 28·65 per cent of total radio-DOPA converted; the calculated incorporation of tyrosine and DOPA without decarboxylation in utilizing both radio-tyrosine and radio-DOPA was 22·31 per cent. The incorporation of tyrosine and DOPA carboxyl groups into melanin is probably due to the copolymerization of tyrosine, DOPA or/and their intermediates with indole-5,6-quinone or that unit of melanin primarily contributed by the attraction between the intermediates. This supports the attraction hypothesis. Furthermore, the greater incorporation of the DOPA carboxyl group than that of the tyrosine carboxyl group can be explained by the attraction hypothesis in addition to the tyrosine-DOPA conversion limiting factor(s).

HABITUATION AT THE SYNAPTIC LEVEL IN *Aplysia*

By DR. J. BRUNER and DR. L. TAUC

Laboratoire de Neurophysiologie Cellulaire du Centre d'Etudes de Physiologie Nerveuse du Centre National de la Recherche Scientifique, Paris, and Institut de Biologie Marine, Arcachon

A DIMINUTION of compound excitatory post-synaptic potentials (EPSP) has been observed in the giant cell in the abdominal ganglion of *Aplysia* on repeated mechanical stimulation applied to the skin of the animal[1] or on repeated electrical stimulation of the afferent fibres[2]. Similar diminution has been observed in the giant cell of the left pleural ganglion[3]. In the present investigation an attempt was made to analyse the mech-

indole-5,6-quinone in acid solution although it is not oxidizable itself into melanin. In addition, direct incorporation of other potentially anionoid substances such as tyrosine or DOPA may also be expected during generation of the indole-5,6-quinone. Considering the basic principle of polymerization analogous to indole–quinone condensation, incorporation of the carboxyl group of tyrosine or DOPA into the melanin polymer[1-5,7] may result from copolymerization of these substances and their intermediates with melanin or precursors prior to decarboxylation. However, the carboxyl groups of the pyrrolic acid units in the melanin polymer originate from the breakdown of the indole benzonoid ring of the polymer[6], and thus are not derived from the carboxyl groups of tyrosine and DOPA.

In melanin formation, the incorporation of radio-DOPA without decarboxylation is much higher than that of radio-tyrosine without decarboxylation. The attraction hypothesis may explain this difference. As the degree of tyrosine or DOPA incorporation into melanin, using fish skin homogenates, is small[8], the amount of radio-DOPA and intermediates present at any time during incubation is also small. The effective concentration of radio-DOPA and intermediates will be much higher at any given time in a system of 40 μg L-tyrosine and 2 μg L-DOPA-^{14}C than in one with 40 μg L-tyrosine-^{14}C and 2 μg L-DOPA. At the beginning of incubation, the effective concentration of L-DOPA-^{14}C is 2 μg/ml. in the former system while it is zero in the latter system. During incubation, the probability that the concentration of radio-DOPA in the latter system does not attain the level present in the former is high for several reasons. The radioactive DOPA concentration in the latter system is reduced by the slow conversion rate of tyrosine to DOPA and, perhaps, partial loss of monophenolase activity in the enzyme preparation[11-13]. The polarity and structure of DOPA is more like that of the diphenolic compounds (or their quinone form) than tyrosine. Therefore, DOPA and its melanogenic intermediates may be more easily copolymerized than tyrosine. An intermediate which may be readily copolymerized is indole-5,6-quinone-2-carboxylic acid, which has been demonstrated in sepiomelanin[2-4]. Since the effective concentration of radio-DOPA is higher in a system utilizing labelled DOPA rather than labelled tyrosine the incorporation of the label by copolymerization will be proportionally higher in the former system.

From the foregoing discussion together with other available information[1-5,7-13], the following conclusions may be reached: (1) Only DOPA or its intermediates may readily be converted into a melanin precursor (indole-5,6-quinone) for polymerization. (2) Only DOPA or its intermediates may easily be attracted by melanin or a melanin precursor for copolymerization. (3) With the catalytic reaction of DOPA in tyrosine–DOPA conversion, enzymatically and/or autoxidatively the incorporation of tyrosine into melanin by polymerization and copolymerization may take place. (4) The direct incorporation of tyrosine into melanin with indole-5,6-quinone or into melanin by copolymerization is not excluded. (5) Both polymerization and copolymerization may be considered, primarily, to result from the attraction of the intermediates during melanogenesis.

Electron spin resonance studies have demonstrated the irregularity of the melanin polymer[14] as first suggested by Swan[7]. A portion of this irregularity may result from copolymerization. Further, during polymerization, cross-linkage may also be responsible for the irregularity[1,7,14] and this may also be produced by attraction at different sites of the same monomer. Thus, the attraction hypothesis may explain the observed irregularity of the melanin molecule by both polymerization and copolymerization. Under these circumstances, it is obvious that the molecular environment in the cell will directly affect the structure of the melanin polymer during melanogenesis. As the intra-cellular environment is in constant flux, the melanogenic end-product will also vary.

In summary, with the use of carboxyl-labelled tyrosine and DOPA, the incorporation of tyrosine and DOPA without decarboxylation into melanin by skin homogenates of black moor goldfish has been demonstrated. Comparison of the results obtained with L-tyrosine-1-^{14}C, DL-tyrosine-2-^{14}C, uniformly labelled L-tyrosine-^{14}C, DL-DOPA-1-^{14}C and DL-DOPA-2-^{14}C, the incorporation of radio-tyrosine without decarboxylation into melanin in the presence of unlabelled DOPA was 9·50 per cent of the total radio-tyrosine converted; the incorporation of radio-DOPA without decarboxylation into melanin in the presence of unlabelled tyrosine was 28·65 per cent of total radio-DOPA converted; the calculated incorporation of tyrosine and DOPA without decarboxylation in utilizing both radio-tyrosine and radio-DOPA was 22·31 per cent. The incorporation of tyrosine and DOPA carboxyl groups into melanin is probably due to the copolymerization of tyrosine, DOPA or/and their intermediates with indole-5,6-quinone or that unit of melanin primarily contributed by the attraction between the intermediates. This supports the attraction hypothesis. Furthermore, the greater incorporation of the DOPA carboxyl group than that of the tyrosine carboxyl group can be explained by the attraction hypothesis in addition to the tyrosine-DOPA conversion limiting factor(s).

HABITUATION AT THE SYNAPTIC LEVEL IN *Aplysia*

By DR. J. BRUNER and DR. L. TAUC

Laboratoire de Neurophysiologie Cellulaire du Centre d'Etudes de Physiologie Nerveuse du Centre National de la Recherche Scientifique, Paris, and Institut de Biologie Marine, Arcachon

A DIMINUTION of compound excitatory post-synaptic potentials (EPSP) has been observed in the giant cell in the abdominal ganglion of *Aplysia* on repeated mechanical stimulation applied to the skin of the animal[1] or on repeated electrical stimulation of the afferent fibres[2]. Similar diminution has been observed in the giant cell of the left pleural ganglion[3]. In the present investigation an attempt was made to analyse the mech-

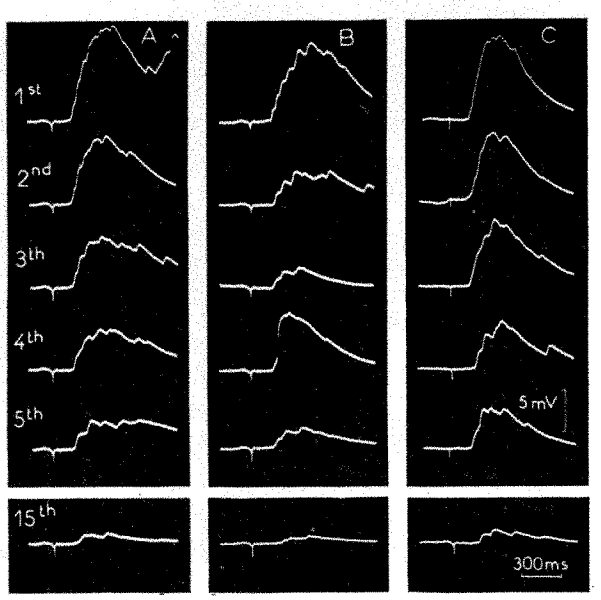

Fig. 1. Modifications of compound EPSP during habituation and dishabituation produced by drops applied at 10-sec intervals on the head near the left anterior tentacle. *A*, First series of fifteen stimuli. *B*, Second series of stimuli showing restoration of the EPSP after 10-min rest. *C*, Continuation of series *B* without break in stimulation frequency but following a 2-sec repetitive stimulation (5 per sec) of the left posterior pedal nerve. Note the restoration of the initial amplitude of the EPSP

anisms of the previously described diminution of EPSP and to relate it to the phenomenon of behavioural habituation demonstrated long ago in other gastropods[4,5].

The experiments were performed on *Aplysia depilans* and *Aplysia punctata*. Part of the central nervous system consisting of the perioesophagial ganglia together with most of the nerves was isolated from the animal body, but in some preparations the head of the animal with the most anterior part of the foot was also excised and the nervous connexions between the cerebral ganglia and the head (designated as cerebral nerves) were maintained. These preparations were mounted in a 'Plexiglass' chamber filled with sea water. The mechanical stimulation was provided by drops of sea water falling from approximately 30 cm on a restricted area of the head, which was kept continuously moist. Intracellular recordings by means of microelectrodes filled with 2·5 M potassium chloride were taken from the giant cell of the left pleural ganglion[6]. The preparations, maintained at room temperature (20°–22° C), showed no detectable deterioration during the 6 to 7 h they were studied.

A drop of sea water applied on the head produced a withdrawal of one or both tentacles. Simultaneously, a 10–15 mV compound EPSP was observed in the giant cell (Fig. 1*A*). Such an EPSP seldom produced a spike. The latency of the tentacular contraction was the same or greater than that of the EPSP. Consequently it can be concluded that the synaptic potentials were not driven by the muscular contraction; nor was the withdrawal of the tentacles dependent on spike activity in the giant cell.

When the drops of sea water were applied at regular intervals (10 sec or more), there was a progressive diminution of both the tentacular response and the compound EPSP (Fig. 1*A*). After fifteen stimulations the EPSP was reduced to 15 per cent or less of its original amplitude. Both responses could be restored by a period of several minutes without stimulation (Fig. 1*B*). The magnitude of recovery depended on the number of stimuli previously administered as well as on the length of the pause. For example, a 10-min rest was nearly sufficient after a series of 10 stimuli. However, when the series was repeated a number of times, with each stimulus series separated by a 10-min rest, it was noticed that the pause became progressively less effective in restoring the original amplitude. After four series of this type, a pause of 50 min restored the EPSP to 85 per cent of its original amplitude. Later series differed from the initial one in two additional ways: the rate of decline of the EPSP was faster, and the terminal EPSP smaller. The tentacular response followed similar kinetics of decrease. The amplitude of the attenuated EPSP could be restored without any rest period either by scratching the skin of the head or electrically stimulating (5–10 per sec for 2–4 sec) one of the nerves or connectives (Fig. 1*C*). The amplitude of the tentacular response could also be restored by scratching the skin, but the tetanization of the nerves was not effective unless the stimulation was prolonged.

The restoration of the compound EPSP by extraneous stimulation suggested the central origin of EPSP 'habituation'. Consequently, it was not surprising to find that the kinetics of diminution and restoration resulting from direct nerve stimulation were similar to those obtained by mechanical stimulation of the skin. Thereafter, this similarity permitted us to use the isolated nervous system for analysis of the mechanism of the EPSP 'habituation', applying the same pattern of stimuli and rest directly to one of the cerebral nerves.

The diminution of the compound EPSP on such a stimulation series was mainly due to an increase in latency and/or the disappearance of the unitary EPSPs which were often distinguishable in the compound potential. It was also noted that simultaneously the amplitude of some of these unitary EPSPs decreased on repetition. It was possible to observe the modification of these unitary potentials in isolation by stimulating the cerebral nerves just at the threshold, resulting in the activation of only one presynaptic interneurone[7]. The fact that the latency of these unitary potentials changed under stimulation at one or two per second, and that they failed to follow at high frequencies, suggest non-monosynaptic connexions.

The changes in the unitary EPSP that occurred under repeated stimulation were very similar to those shown by the compound EPSP. As for the compound potentials, the unitary potentials showed a diminution in amplitude

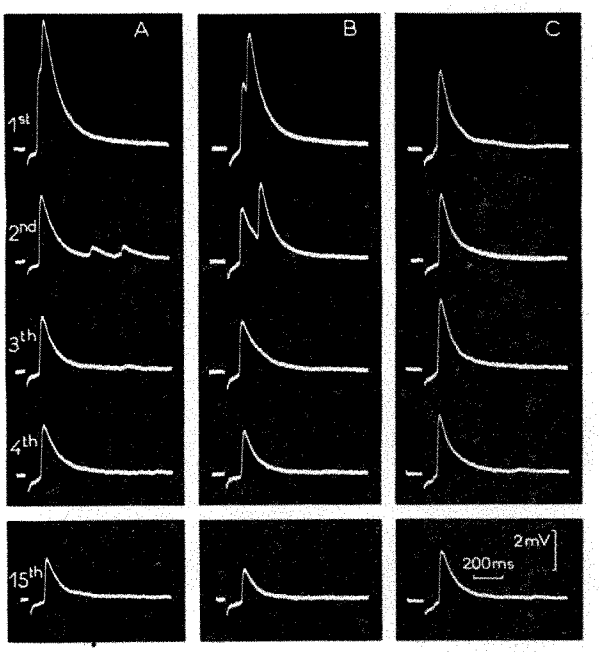

Fig. 2. Modifications of unitary non-monosynaptic EPSP produced by electrical stimuli at 10-sec intervals, applied to one of the left cerebral nerves (small tegumentary nerve). *A*, First series of fifteen stimuli. At the beginning of this and the next series other EPSPs superimposed first unitary EPSP. *B*, Restoration of the unitary EPSP after 10-min rest. *C*, Restoration of the unitary EPSP produced by 3-sec repetitive stimulation (10 per sec) of another left cerebral nerve (posterior tentacular nerve)

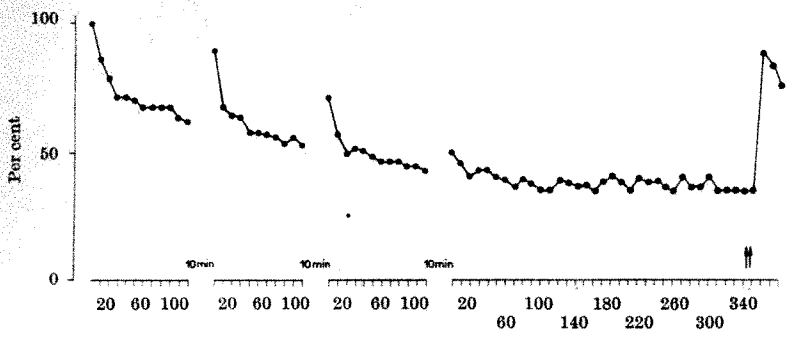

Fig. 3. Accumulation of effects of stimulation (at 10-sec intervals) on recovery process observed in a unitary monosynaptic EPSP. Ordinate: Percentage of amplitude of initial EPSP. Abscissa: Time (in sec and min). Arrows in final series indicate occurrence of 3 sec tetanization of left posterior pedal nerve; note slightly delayed recovery of EPSP

within a stimulus series (Fig. 2*A*). Moreover, as before, the amplitude of the attenuated potential could be restored either by rest or by electrical stimulation of one of the nerves or connectives (Fig. 2*B* and 2*C*). Successive rest periods were increasingly ineffective in restoring the original EPSP amplitude.

Unitary potentials which appeared to be monosynaptic were obtained by stimulation of the left pleuro-visceral connective[8]; and these EPSPs showed identical changes to those already described (Fig. 3).

Such modifications of unitary EPSPs on the level of interneurones would explain the inability of the latter to give a propagated spike after a few stimuli, which in turn would result in the increase in latency and the disappearance of some individual elements in the compound EPSP (see Fig. 2). But it should be noted that the described properties of EPSPs were observed only in some cells. The EPSPs of other *Aplysia* cells do not show a decrease on repeated stimulation at low frequency[9].

The mechanism of this depression of unitary EPSPs is obscure. It is difficult to attribute a post-synaptic character to this phenomenon; indeed, the physical constants of the post-synaptic membrane were demonstrated to remain unchanged during repetitive stimulation of the afferent fibres. Moreover, the hypothesis of a possible desensitization of subsynaptic receptors[10,11] would be incompatible with the recovery of the EPSP after brief tetanization of the same input. Presynaptic inhibition, which was also demonstrated in *Aplysia*, seems not to be responsible for the 'habituation' of the EPSP, as the corresponding effects of pre-synaptic inhibition are less and less effective[9], contrary to the effects of accumulation observed in these experiments. It seems more likely that the decrease is due to a diminution of transmitter release, probably caused by the depletion of the transmitter in the terminals and its slow mobilization. We have frequently observed that, after one stimulus, a diminution of the subsequent EPSP amplitude could be detected even after 3–4 min. In some respects the phenomenon is similar to the depression observed in some other synapses and especially in neuromuscular synapses[12–14], but it differs in its much longer time course as well as in the long lasting dependence on previous stimulation.

The restoration of the EPSP by a brief tetanization of the same or different nerve seems to be provoked either by post-tetanic potentiation[15] or by heterosynaptic facilitation observed in a group of cells in the abdominal ganglion of *Aplysia*[8].

Hence the modifications of EPSPs of the giant cell observed during habituation to a repeated mechanical stimulus seem to be due to long-lasting changes in synaptic efficacy. Despite the fact that the giant cell is not situated in the reflex arc of the tentacular response, the similar kinetics of the amplitude modifications of the contraction and of the EPSPs suggest that this synaptic mechanism may be one of the elements of behavioural habituation.

FORMATION OF NEW SITES OF ACETYLCHOLINESTERASE ACTIVITY IN DENERVATED MUSCLES OF YOUNG RATS

By Prof. LILIANA LUBIŃSKA
Department of Neurophysiology, Nencki Institute of Experimental Biology, Warsaw
AND
Dr. JIŘINA ZELENÁ
Physiological Institute of the Czechoslovak Academy of Sciences, Prague

When an adult mammalian skeletal muscle is denervated, the activity of acetylcholinesterase at its motor end-plates gradually decreases[1] whereas that of muscle–tendon junctions remains unchanged[2,3].

If the denervation is carried out in the rat at birth or shortly afterwards, the fall of activity at the end-plates is more abrupt[4,5] and, contrary to what was observed after denervation in the adult, no acetylcholinesterase (AChE) activity is seen at the myotendinous junctions[6]. The changes in the acetylcholinesterase activity of the muscle, however, are not confined to these loci. About 2 weeks after denervation, new spots of fairly intense acetylcholinesterase activity make their appearance. They are scattered over the muscle some distance from the line of end-plates (Fig. 1).

Although the number and spatial dispersion of these spots make it unlikely that they correspond to incipient end-plates produced by an uncontrolled nerve regeneration such a possibility was discarded by experiments in which a permanent motor denervation of limb muscles was

Table 1. COMPARISON OF MUSCLE FIBRES FROM THE TIBIALIS ANTERIOR OF RATS DENERVATED AT BIRTH WITH NORMAL TIBIALIS FIBRES AT SIMILAR AGES*

Days after birth	Muscle	Length of muscle (mm)	Fibre diameter (μ)	Length of end-plate (μ)	Ratio: end-plate length to fibre diameter	No. of additional active spots on a fibre	Length of active spots (μ)
0	normal	4·1	5·9 ± 0·2	18·4 ± 0·6	3·10	0	—

* About seventy isolated fibres from two animals were measured at each age. The diameters of fibres were measured in their cylindrical part, far from the terminal taperings. The dimensions of end plates are those of their AChE-stained portions.

obtained by removal at birth of the lumbar and sacral parts of the spinal cord[6]. The resulting irreversible de-efferentation produced an outcrop of new spots of AChE activity similar to those observed after section of the nerve.

The distribution and appearance of AChE-active sites was studied in individual fibres teased after incubation of the whole muscle with acetylthiocholine by a slightly modified Silver[7] method.

In the denervated muscle the diameter of fibres increases more slowly with age than that of normal muscle fibres. Striking changes occur at the end-plate, where AChE activity falls considerably, and the sole becomes straight and about three times longer than a normal end-plate at this age (Fig. 2*a*, *b*). At various distances from the end-plate, small cytoplasmic elevations bulge over the surface of the fibre. Some of these show much stronger cholinesterase activity than does the denervated end-plate (Fig. 2*c*, *d*). Structural details in the active spots are obscured by the large amount of stained granules, but sometimes a nucleus may be discerned inside the cytoplasmic hillock or nearby. These spots are always sharply outlined and sometimes seem to adhere to the surface of the fibre rather than to protrude from the inside. Although the spots are usually separated by large distances (0·5–3 mm), two spots occasionally appear in close proximity (Fig. 2*d*).

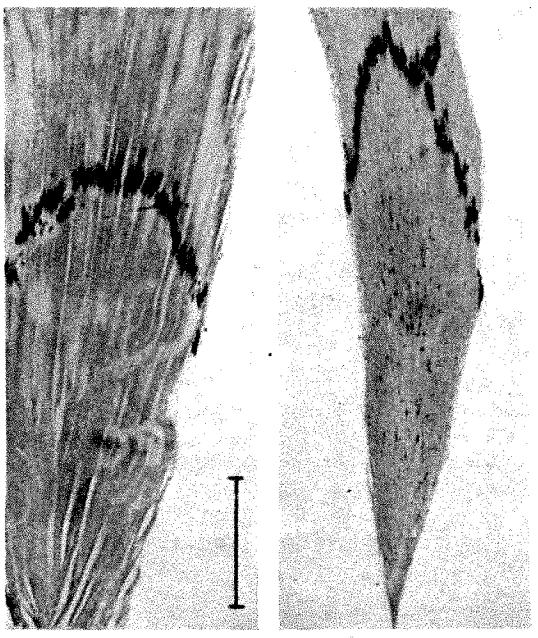

Fig. 1. Longitudinal sections of the tibialis anterior muscles of 21-day old rats. Left, normal. Right, denervated at birth. Stained for AChE by a modified Koelle and Friedenwald (ref. 18) method, after pre-incubation with 3×10^{-7} M di-isopropylfluorophosphate. Additional spots of activity are scattered in the denervated muscle some distance from the line of end-plate. Scale, 2 mm

The zones of muscle fibres in which the additional spots of AChE activity are mainly distributed are shown in Fig. 3. These zones do not seem to vary with age within the period investigated, except for the elongation due to growth. The number of additional spots in muscle fibres does not vary significantly with age between 17 and 32 days.

The ability to form new foci of AChE activity seems to be connected with a certain stage of development of the muscle. Denervation in the adult does not produce these foci. It seemed valuable, therefore, to characterize certain features of muscle fibres at birth, at the moment of denervation, and to compare the further development of denervated fibres producing additional spots of activity with normal muscle fibres at similar ages. The results of measurements made on fibres from the tibialis anterior muscle are summarized in Table 1.

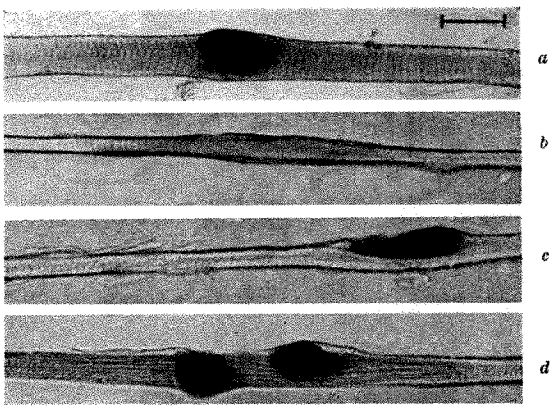

Fig. 2. Parts of isolated muscle fibres from the tibialis anterior of 21-day old rat. *a*, Normal end-plate; *b*, denervated end-plate; *c* and *d*, additiona spots of AChE activity in denervated fibres. Stained for AChE by acetylthiocholine method. Incubation times and photographic processing identical in all fibres. Scale 25μ

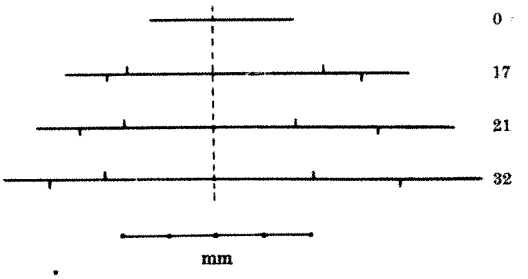

Fig. 3. Diagram showing the average length of fibres from the tibial anterior muscle at birth and at 17, 21 and 32 days after denervation. The vertical line indicates the position of the end-plates which are not in the middle of fibres in this muscle. The upward dashes indicate the average distance of the nearest spot from the end-plate, the downward ones that of the farthest spot. Twenty to thirty fibres were measured in each muscle

It is difficult to interpret the formation of new spots of AChE activity in young denervated muscles. No focal accumulations of AChE were found in embryonic muscles before innervation[8] or in chick muscle in tissue culture even at an advanced degree of differentiation of muscle fibres[9]. Rat muscles do not seem to have been investigated under these conditions. However, as the first effect of denervation of a developing rat muscle is the dispersal of AChE at the end-plates and at myo-tendinous junctions, the formation at later stages in other parts of muscle fibres of new foci of AChE activity caused by the same factor is surprising. It is not clear whether the AChE activity is actually concentrated in sarcoplasmic bulges or in the protoplasm of some cells closely adhering to the surface of muscle fibres. Light microscope investigations of whole teased fibres, as well as of muscle sections, were technically inadequate to decide this question.

The fact that the additional spots appear only if the muscle is denervated at a certain stage of its development and that they are clustered only in certain regions of the muscle suggests that it is the denervated muscle fibre itself that produces focal accumulations of AChE in its sarcoplasm. Other possibilities are, however, not excluded. A possible non-myogenic source of the active spots might be from the Schwann cells of the degenerating intramuscular nerve branches. As is well known[10,11] the Schwann cells become migratory after the breakdown of their axons and it is possible that they could creep along the surface of muscle fibres, closely applied to them. Although in normal nerves the Schwann cells are devoid of AChE activity[12,13] the ability to produce AChE may appear some time after denervation. This is suggested by the observations that the intra-muscular branches of degenerating nerves show positive staining for AChE several weeks after denervation whereas normal nerves are not stained under similar conditions[14,15].

It is of interest in this connexion that the possibility of acquisition by the Schwann cells of a mechanism for synthesis and destruction of acetylcholine has been invoked to explain various phenomena observed in the late stages of denervation, such as the reappearance of miniature end-plate potentials after a silent period in the frog[16], or the increase of choline-acetylase activity in denervated salivary glands[17] that follows an initial fall of activity of this enzyme.

ROLE OF MITOSIS AND MITOTIC INHIBITION IN THE IMMUNOSUPPRESSIVE ACTION OF THIOGUANINE

By DR. M. C. BERENBAUM

Surgical Unit, St. Mary's Hospital Medical School, London

IT is well known that antibody-forming cells undergo mitosis during the early stages of the immune response[1] and that many immunosuppressive agents are inhibitors of mitosis[2]. These facts have led to the common assumptions (*a*) that the increase in antibody-levels after antigenic stimulation may be accounted for quantitatively by the rapidly repeated divisions of antibody-forming cells, and (*b*) that the effects of immunosuppressive agents may similarly be accounted for by their ability to prevent mitosis. This article suggests that one or both of these propositions is incorrect.

Conventional measurements of levels of immunity, that is, antibody titres, intensities of hypersensitivity reactions or rates of homograft rejection, reflect the cellular events of the immune response only with a considerable delay and insensitivity. This gives rise to great difficulty in analysing the effects of immunosuppressive agents. For example, the characteristic delayed appearance, reduced rate of growth and reduced peak of the partly suppressed response could be caused by a variety of cellular effects. These include cell destruction, overall slowing of the response (due, for example, to mitotic inhibition) and a delay in initiating the response with one or more of its components undergoing a natural decay. However, measurements of levels of immunity have not so far made it possible to indicate with confidence which, if any, of these mechanisms is responsible for suppression of the response.

Techniques devised[3,4] for counting the numbers of antibody-forming cells in various tissues seem to offer a possible method of examining more directly the effects of immunosuppressive agents on the cells concerned.

Male *A2G* mice, weighing 15–21 g at the beginning of each experiment, were injected intraperitoneally with 0·2 ml. of 10 per cent formolized sheep red cells in saline. At intervals after the injection, groups of mice were killed and the number of haemolysin-producing cells in their spleens counted by Jerne's agar-plating technique[5]. Plates were incubated at 37° C for 1 h, 10 per cent guinea-pig serum in saline added and the haemolysed plaques counted after a further 30-min incubation.

The combined results of several experiments are shown in Figs. 1 and 2, the counts on individual spleens in the former and the geometric means of the counts in the latter. Unimmunized mice had about fifty plaque-forming cells per spleen. The number rose slightly to about ninety 1 day after immunization and then rapidly to a peak of 30,000 on the fourth day. The doubling-times were 9·2 h between days 1 and 2, 6·8 h between days 2 and 3 and 9·8 h between days 3 and 4. After the fifth day there was a fall that slowed progressively and the number of haemolysin-forming cells dropped to 150–300 by the third week.

Thioguanine was selected for investigation as an immunosuppressive agent as it is highly effective in inhibiting antibody production in relatively non-toxic doses[5] and does not cause gross destruction of lymphoid tissue which might make interpretation of results difficult[6]. The agent was ground in 0·5 per cent carboxymethyl-cellulose in normal saline and injected subcutaneously in doses of 10–240 mg/kg body-weight. Injections were

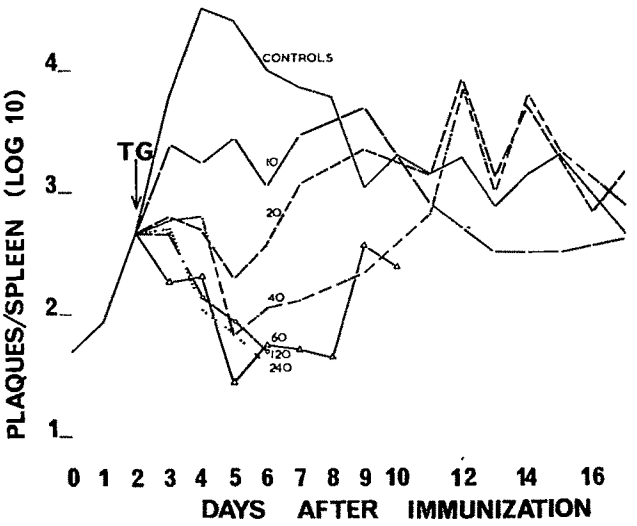

Fig. 2. Effects of various doses of 6-thioguanine, given subcutaneously on day 2, on the number of haemolytic plaques per spleen. ——, Controls; — — —, 10 mg/kg; — — — — — —, 20 mg/kg; —·—·—·—·—, 40 mg/kg; ——Δ——Δ——, 60 mg/kg; O——O——O, 120 mg/kg; ····· , 240 mg/kg. Curves show the geometric means of each group of counts. Numbers of counts: controls as in Fig. 1, 10 mg/kg—three mice/day, 20, 40, 60, and 120 mg/kg—five to nine mice/day at each dose level, 240 mg/kg—twenty or twenty-one mice/day

given 48 h after the antigen, as this is the optimum time for inhibiting antibody production with a single dose of agent[7]. Doses of 20 mg/kg or more caused a fall in the number of haemolysin-producing cells that reached its lowest point within 3–4 days and was followed by a slow rise toward normal levels (Fig. 2). A maximum rate of fall was produced by doses of 60 mg/kg or more.

The results of four experiments relevant to the assumptions outlined above are shown in Fig. 3. In these experiments, administration of 60–240 mg/kg thioguanine was followed by a fall in the number of antibody-producing cells, the halving time varying from 7·8 to 13·6 h. Arrest of mitosis cannot of itself have caused this fall unless the cells underwent a natural wastage due to death, cessation of antibody-synthesis or migration elsewhere. If, however, this wastage was natural and not caused by the thioguanine it must also have occurred during the normal, unsuppressed response. Accordingly, the increase in antibody-forming cells after antigenic stimulation was achieved in spite of a natural wastage and their generation time must have been even shorter than that suggested by their observed rate of increase.

It has been suggested that a major factor limiting the rapidity of cell multiplication is the time needed for the cell to synthesize a full complement of DNA[11]. The minimum times quoted for this process are 5·5 h in mouse thymus large and medium lymphocytes[8], 6 h in mouse lymphoma cells[8], 6·5 h in mouse trophoblast[9] and 6–7·5 h in various normal tissues and tumours of the adult mouse[10,11]. As the rest of the cell-cycle, including mitosis, takes at least an hour, it would appear that the shortest possible generation time for mammalian cells is 6–7 h. In fact, the generation time of rapidly dividing mammalian cells is more usually 12–18 h[11], but a few shorter times have been recorded, for instance 6·8 h for mouse thymus large lymphocytes[8], 7·6 h for mouse lymphoma cells[8], 8·2 h for mouse thymus medium lymphocytes[8] and 9·6 h for mouse trophoblast[9]. The rate of increase of haemolysin-producing cells between days 2 and 3 would therefore appear to be about the fastest that is compatible with cell-division.

Allowance for natural wastage may be made as follows. If, in antigenically stimulated animals, the number of antibody-forming cells rises exponentially from A to B in time t, the observed doubling time being OT_2, and, in such animals after administration of an immunosuppressive agent, falls from C to D over the same period, the observed halving time being $OT_{\frac{1}{2}}$, and if it is assumed that this fall is due only to a natural wastage that is uncovered when the agent stops cell division, it can be shown that the true doubling time of the cells, T_2, is given by

$$T_2 = \frac{OT_2 . OT_{\frac{1}{2}}}{OT_2 + OT_{\frac{1}{2}}}$$

$$\text{and } T_2 = \frac{t . \log 2}{\log B + \log C - \log A - \log D}$$

When the start of t is at the time of administration of the agent, then $A = C$ and

$$T_2 = \frac{t . \log 2}{\log B - \log D}$$

In this case it is necessary to perform cell counts only at the end of the treatment period; the starting level is irrelevant.

The values of the observed doubling and halving times for each of the four experiments are noted in Fig. 3. The estimated true doubling times, given the assumptions stated, vary from 5·5 h down to 3·6 h. In the light of

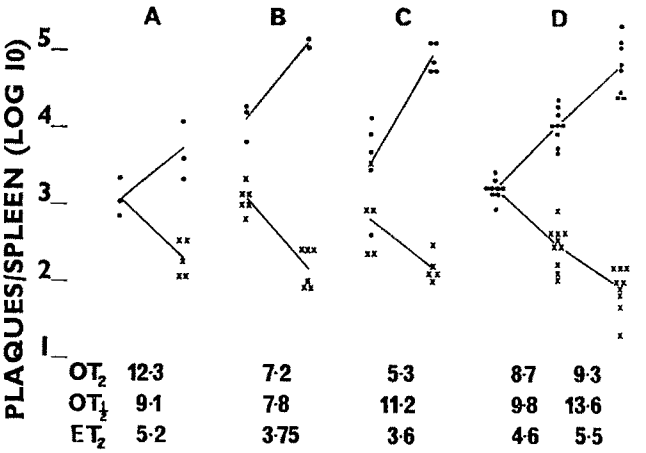

Fig. 3. Reduction in number of haemolytic plaques per spleen after administration of 6-thioguanine on day 2, compared with the increase in untreated mice. Each point represents the count on one spleen; the curves are drawn through the geometric means of each group. ●, Control mice, X, treated mice. Doses—60 mg/kg in experiment A, 240 mg/kg in experiments B, C and D. Counts performed on days 2 and 3 in experiment A, days 3 and 4 in experiments B and C and days 2, 3 and 4 in experiment D. OT_2—observed doubling time of haemolysin-producing cells in control mice; $OT_{\frac{1}{2}}$—observed halving time of haemolysin-producing cells in thioguanine-treated mice; ET_2—estimated true doubling time (see text)

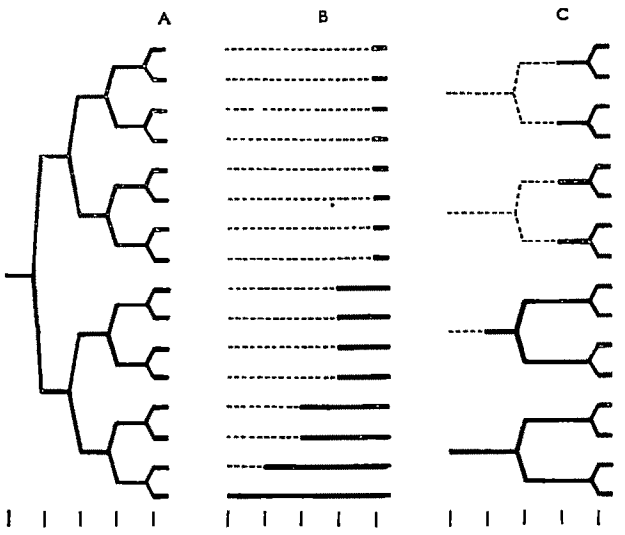

Fig. 4. Three possible ways in which the number of haemolysin-forming cells could increase, the observed rate of increase being the same in each case. — — — — — —, Cell not producing antibody, ———, cell producing antibody. In *A* there are four consecutive divisions in the period shown and one antibody-producing cell multiplies to form 16. In *B* antibody production begins at different times in 16 non-dividing cells. In *C* there are two consecutive divisions in the period shown, four cells multiplying to form sixteen, and antibody production begins at different times in the four dividing cell lines

present knowledge of the minimum times required by mammalian cells to synthesize DNA and proliferate, such doubling times cannot be ascribed to cell division alone.

It follows that one or both of the original assumptions must be wrong. If the increase in antibody-forming cells is due entirely to cell-division, the decrease after administration of thioguanine cannot be due to a natural wastage that becomes observable only when mitosis is stopped but must be due to destruction of cells or impairment of their ability to produce antibody. Conversely, if thioguanine acts only by stopping mitosis, the rapid increase in antibody-forming cells in the early stages of the immune response cannot be due entirely to cell-division.

Three possible modes of increase of antibody-forming cells are shown in Fig. 4. All give the same observed doubling time but in *A* the increase is due entirely to cell division, in *B* entirely to induction of antibody-formation at different times in initially non-producing cells[3] and in *C* to a combination of both mechanisms. For clarity these models do not take cell wastage into account, but they may readily be adjusted to allow for this factor. As has already been shown, model *A* is credible only if immunosuppressive agents, whatever their effects on mitosis, also destroy cells or prevent them from synthesizing antibody. In model *B* there is no cell-division and the effects of immunosuppressive agents must be ascribed to cell destruction (either alone or combined with natural wastage) or to destruction and/or wastage combined with inhibition of induction or antibody synthesis. This model, however, is unacceptable in its simple form, as antibody-forming cells undoubtedly multiply by the conventional processes of DNA synthesis and mitosis[1]. In model *C*, the cell generation time may be assigned acceptable values, for example 7–12 h, and the shorter observed doubling time of antibody-forming cells achieved by the induction of antibody synthesis at different times during the proliferation of initially non-producing cells.

In this model, the effects of immunosuppressive agents could be due to any of the mechanisms postulated for model *B* and also, under some circumstances, to mitotic inhibition alone. If, for example, induction were mitosis-dependent, simple mitotic arrest would stop the appearance of new antibody-producers and their numbers would then fall by natural wastage. If induction were mitosis-independent, simple mitotic arrest could still cause the number of antibody-producers to fall if the induction that continued in the population of non-dividing cells did not keep pace with natural wastage. In the latter case, however, by a similar argument to that used above, it would follow that the fall in number of antibody-producing cells after administration of thioguanine occurs in spite of continued induction of new antibody-producers and that the true half-life of these cells is shorter than the halving times observed.

The results reported here do not disprove the hypothesis that immune processes are accounted for quantitatively by a wave of cell division that follows antigenic stimulation, nor that which ascribes the effects of immunosuppressive agents to mitotic inhibition. They do show, however, that these hypotheses are incompatible with each other.

LABORATORY REARING OF THE PARASITIC STAGES OF *Boophilus decoloratus* (KOCH, 1844) ON THE EUROPEAN RABBIT (*Oryctolagus cuniculus*)

By V. AMMAH-ATTOH
Animal Research Institute, Ghana Academy of Sciences, Achimota, Ghana

WHILE endeavouring to breed *B. decoloratus* (Koch, 1844) on its principal host, the ox, I experienced great difficulty in obtaining information on the durations of development of the various parasitic stages of the life-history of this tick species. Therefore, both the guinea-pig and the rabbit were tried as experimental hosts. The larvae of *B. decoloratus* were able to become established on the rabbit, but not on the guinea-pig. The latter was therefore discarded in preference for the rabbit.

The larvae used for the infestation of the rabbit were bred from eggs that were incubated in the laboratory at a temperature ranging between 76° and 88° F (ref. 1). The humidity in the incubation chambers (that is, glass specimen tubes), in which the laying female tick species

were individually placed, was maintained by moistening cotton-wool stoppers at convenient intervals. The larvae were starved for about 2 weeks once their cuticle had hardened and then fed on the rabbit.

The rabbit was infested by the following technique. The experimental host was placed in a cylindrical glass jar with a lid. The larvae, which had been warmed in their tubes to ordinary laboratory temperature, following a period of inactivation in the refrigerator at 59°–68° F, were transferred to the body of the rabbit. Any larvae crawling on the inner surface of the jar were picked up with a fine camel hair brush and placed on to the rabbit. Airing of the glass jar occurred simultaneously. Constant observations were made until almost all the larvae had become attached to the body of the host. Three hours later, the rabbit was transferred to a small glass container inside a box made of mosquito-proof wire mesh. The host was fed mostly with pelleted roughage and water. Ticks which fell off the host were collected before any debris was removed from the cage. On the fourth day after infestation, when the engorged larvae were ready to detach from the host, the latter was transferred into a ventilated rectangular glass container from which the larvae were collected as they dropped off the host. The replete larvae were stored in the laboratory and the newly moulted nymphs resulting from them were also fed on the rabbit, using the same technique.

When the larvae of *B. decoloratus* became established on the rabbit the results showed that the tick behaved rather unusually as a three-host and as a two-host tick species. These behaviour patterns are discussed below.

The larvae became fully engorged, dropped and moulted off the host's body. It has been shown in Table 1 (*a*) that at the recorded mean laboratory temperatures, which appeared to be fairly similar, the average feeding period for 2,296 larvae was 4·2 days (range 3–5 days). Most of the larvae, that is 1,543, became fully engorged in 4 days and dropped off; 296 engorged fully and dropped off in 5 days, while the rest, namely 457, engorged and dropped off in 3 days.

Table 1. LARVAL STAGE: DURATION OF DEVELOPMENT OF IMMATURE STAGES OF *Boophilus decoloratus* (KOCH, 1844)

(*a*) Feeding on rabbit

No. of mother tick	Date of infesting host	Date engorged larvae dropped off the host	No. of engorged larvae dropping off	Laboratory temperature (° F) Range	Mean	Duration of feeding of larvae (days)

				Totals	(1,791)	(175); Av. 17·5

Table 1 (*b*) shows that during an average period of 17·5 days (range 15–22 days), 1,791 engorged larvae metamorphosed into nymphs off the host's body at the average laboratory temperatures of from 77·4° to 79·8° F. Most of the larvae, 795, metamorphosed into nymphs within 17 days; 363 moulted within 16 days, and the third largest number, 272, moulted in 15 days.

As already stated, such newly moulted nymphs, having hardened within 3–6 days, were also experimentally fed on the same rabbit. They engorged fully and fell off the host at the rates recorded in Table 2 (*a*). 101 nymphs fed fully and dropped off within an average of 7 days (range 4–10 days), when the mean laboratory temperature varied between 77° and 81·1° F. About 50 per cent of the engorged nymphs dropped off within 4 days and the next largest number of engorged nymphs (27) fell off in 5 days. It will be seen that 76 out of 101 of the engorged nymphs were collected in the morning.

			18 9	4	70–84	77·3	23
			19·9	24	70–84	77·4	24
			Total	(79)			(160) Av. 22·9

The average pre-moulting period for 79 engorged nymphs has been recorded in Table 2 (*b*) as 22·9 days (range 18–29 days), within the narrow average laboratory temperature of from 77·4° to 77·9° F. If the rather small number of four engorged nymphs that moulted off the host's body during the longest period of 29 days is ignored, it is clear that the largest quantity of nymphs (34) metamorphosed within 22–23 days at an average laboratory temperature of 77·3° F. Twenty-four moulted in 24 days at an average temperature of 77·4° F, while fifteen changed into adults during 18–19 days at 77·9° F. Only two moulted in 25 days at 77·7° F.

Twenty females from this stock of laboratory-bred adults having hardened in 3–5 days were placed on the ear of the rabbit in order to ascertain the average feeding period of these adult ticks. They attached to the experimental host within 3 h (unlike the larvae and nymphs which attached in less than 2 h) and fed slowly for 5 days. Without becoming even partially engorged, they detached on the fifth day and were collected in a polythene bag. It was thus not possible to obtain any conclusive information on the duration of the feeding period of the female tick.

Supplement to NATURE

No. 5031 APRIL 2, 1966 Vol. 210

SCIENCE, MAN AND MORALS

Science, Man and Morals

By Dr. W. H. Thorpe. (Based upon the Freemantle Lectures delivered in Balliol College, Oxford, Trinity Term, 1963.) Pp. xii + 176. (London: Methuen and Co., Ltd., 1965.) 25*s*. net.

THE central themes of *Science, Man and Morals* are defined by the author as "the process of creation" and "the growing understanding of the unitary foundation underlying all experience—scientific, artistic and religious"; but these are dry bones which he brings to life.

Prof. Thorpe assembles an impressive array of evidence, mathematical as well as biological, to prove the fantastic improbability of the idea that the origin of life, or even the simultaneous formation of two or more molecules of any given enzyme, occurred purely by chance. Nor can the emergence and existence of mind be explained in terms of the laws of physics and chemistry. These laws must be obeyed but they do not require the self-consciousness which is the most convincing knowledge that we all have of ourselves. As a world authority on animal behaviour, Prof. Thorpe is eminently able to trace the development of social life and the importance of psychic factors in determining the evolution of human cultures. Moreover, in order to understand the beginnings of abstract ideas and of the language by means of which these may be expressed and communicated, the author has found it helpful to study animal communication, since in many ways the difference between the minds of men and of animals seems to be one of degree.

It is a far cry, however, from a scholarly discussion as to how early ideas came to include primitive ethical concepts, to the pressing modern ethical problems raised by the population explosion, artificial insemination, selective breeding, the welfare state, the uncontrolled exploitation of natural resources, personal problems such as chastity, monogamy and homosexuality and the immediate and imperative problems of aggression and war. Prof. Thorpe does not avoid any of these, but feeling, as he does, so strongly about aggression and war, one could have wished that he had given more than five pages to it.

The discussion of moral, as distinct from ethical, problems brings us into the domain of theology since "there can be no temptation to consider moral concepts as such as derivable from the scientific picture of the origin and development of the living world". Is there any necessary relationship between primitive magic—superstitious behaviour—and religious awareness? It seems not. Religious awareness appears to be a much later development of the search for understanding for its own sake. In spite of the complexities of the modern scientific world picture, the scientist remains obstinately convinced that he is dealing with a real, external world. Religious intuition, the direct knowledge of a world infinitely greater than, but in some sense sympathetic to, ourselves is more nearly akin to the approach of the artist than to that of the scientist, at least in so far as "artistic values are not just the expression of feelings and attitudes . . . but are in fact engendered in the process of establishing a relation with an objective reality transcending ourselves. . . . In theology, the mystical awareness of God as the whole, in some sense the unity of all things, is in effect the basis of all the fundamentals of belief".

The idea of wholeness and the related concept of perfection are shared by a number of religions, but the core of the teaching of Christ is that God is Love and that the greatest achievement of human life is self-effacing love. Moreover, that personality, so far from being a finite attribute of finite beings, is an ideal conception, "the highest category of unity in diversity which we know". "There is a fundamental Christian conviction that somehow there is a realm in which what ought to be is what is; . . . it is impossible to conceive moral judgments being made where there is no moral agent; and a moral agent implies personality."

This is a very inadequate summary of a book that covers a very wide field. It is extremely well documented and the "Notes" which include and amplify the references are well worth reading. The anecdotal illustrations are few but good, and perhaps a non-biological scientist may be excused for wishing that there could have been rather more of them and less quotation from other authorities, even though the quotations are always relevant. The part of the argument that comes through most forcibly is that in which the author expresses his own convictions: and conviction is usually caught, not taught.

KATHLEEN LONSDALE

BRITISH STATESMEN OF SCIENCE

Statesmen of Science

By J. G. Crowther. Pp. xiii + 391 + 10 plates. (London: The Cresset Press, 1965.) 42*s*. net.

THE present place of science and technology in national life has not been easily won. Nor has it been won by those of us now working comfortably in well-equipped laboratories. The victory, in so far as it has been a victory, was won by our predecessors, who showed by their working examples, against the odds, something of what science and technology could do for civilization. They battled with the prejudice of the classical establishment and with the complacency of manufacturers. Most of us to-day are too busy with research, teaching or administration to give much thought to the account of the battle; but this is a pity, for the account is of vital interest. Hitherto, it has had mainly to be sought among contemporary documents, but Mr. Crowther's newest book provides an easy and illuminating access.

Statesmen of Science is a sequence of concise biographies of nine of the principal figures in the battle during the past century and a half: Brougham, Grove, Playfair, Prince Albert, the Duke of Devonshire, Strange, Haldane, Tizard, and Lindemann. Not only are the nine portraits well drawn, but, in addition, around these central figures are ably sketched many others—including Anderson, Babbage, de la Beche, Birkbeck, Faraday, John Herschel, Huxley, Lockyer, Kelvin, Peel, Rayleigh and Roscoe.

Mr. Crowther tempts us to join him in a Baconian analysis of the common factors in the backgrounds of the nine principal figures. Brougham and Haldane, indeed, emulated Francis Bacon as Lord Chancellors who were interested in science and its promotion. Like them, Grove was a lawyer, but was also a practising scientist and the

inventor of the fuel cell. Brougham, Haldane and Playfair were educated in Scotland (Lindemann was at preparatory school there, too) while Strange was of Scottish blood. Playfair, Prince Albert, Haldane, Tizard and Lindemann received part of their education in Germany; and of the nine, Oxford can claim as undergraduates no more than two—Grove and Tizard—and Cambridge but one, the brilliant Duke of Devonshire, second wrangler and Smith's prizeman of 1829 and donor of the Cavendish Laboratory. Prince Albert, Strange, Haldane, Tizard and Lindemann all had direct concern with military affairs and the applications of science to war. Strange and Lindemann contributed to instrument design, and Grove, Playfair and Tizard to fuel technology.

What the analysis does suggest is that these statesmen of science had to draw much of their inspiration from outside England, even though in pure science England was making outstanding contributions. Mr. Crowther suggests that had Britain seen to it that its scientists of the nineteenth century should live and work "within an adequate scientific order", it might not to-day have become a second-class power, and that failure to create this order was "due to the inhibiting effect of principles that are inherent in capitalist society". Certainly we ought to have done much better than we have, especially when to the voices of science were added those of such humane distinction as Jowett, Matthew Arnold, Mark Pattison, the Webbs, and Robert Bridges. But is it clear that the halting response was due to capitalism? Why, if so, did science flower uniquely in a European culture? Is it capitalism that has contributed to the trend noted by Mill: "the general tendency of things throughout the world is to render mediocrity the ascendant power among mankind"? And Mill could say, even in his day: "The greatness of England is now all collective; individually small, we only appear capable of anything great by our habit of combining . . . But it was men of another stamp that made England what it has been; and men of another stamp will be needed to prevent it decline".

Alternative reasons to Mr. Crowther's can be found for the long apathy of Britain: one of much interest has been offered by Sir Peter Medawar in his sensitive Tizard Lecture on "Anglo Saxon Attitudes" (*Encounter*, August, 1965). But whether Mr. Crowther is right or not in his conjecture, he has given excellently fair portraits of even those of his subjects such as Lindemann, whose political views were quite different from his own. He has written with an appreciative eye for obscure but important detail, with an obvious regard for accuracy and balance, and with a sympathy that transcends politics. One of his heroes, Lyon Playfair, wrote in valediction, "I now feel that this work may be left to younger men, but I hope that they will not take their hands from the plough until England has adapted its system of education to the changed conditions of competition". Even now, there is still much to be done, and Mr. Crowther offers the present generation in science much insight into its ancestry and responsibilities.

R. V. JONES

ANCIENT CHINESE TECHNOLOGY

Science and Civilization in China

By Dr. Joseph Needham, with the collaboration of Dr. Wang Ling. Vol. 4: Physics and Physical Technology. Part 2: Mechanical Engineering. Pp. lv+759+plates 124–281. (London: Cambridge University Press, 1965.) 190*s*. net.

VOLUME 4, Part 2, of Needham's monumental *Science and Civilization in China* is concerned with what is called 'mechanical engineering' in the West. It is pre-scientific technology, however, for the theory of mechanics was unknown to the Chinese. They never arrived at an atomism and the idea of a mechanical particle did not arise in Chinese thought. Instead, they developed a kind of continuum conception similar to the *pneuma* of the Stoics; the living human body rather than the machine was the analogy in terms of which the Chinese saw the world. The continuum favours the study of wave motion and, in consequence, optics, acoustics and magnetism were the branches of physics best known in China. Mechanics was little studied and dynamics unknown. Thus, their engineering—although mechanical in the sense that it is concerned with levers, gears and simple machines based on their use—is, like all Chinese technology, pre-scientific. It is not the application of a theory but practical work arising from artisanship and designed for a specific job.

A vast range of implements is surveyed in this book, from levers and pulleys to clocks, power supplies and the kite. A wealth of detail is given and copiously illustrated; and the book is beautifully produced.

It may well be that more inventions than gunpowder, paper and the compass have come to the West from China though it is doubtful, I think, whether there was direct transmission. Similar devices must have arisen spontaneously and independently in many civilizations simply because they represent a practical means of coping with a problem. To assign priorities seems an almost impossible task; so much depends, too, on what item we are willing to accept as a legitimate precursor of a given device. The invention of a mechanical clock is generally credited to Europe and, in the first volume of the present work, Needham himself accepted this view; he feels now, however, that he must reject it. An astronomical clock tower was built by Su Sung in A.D. 1090. The clockwork, driven by a waterwheel, rotated an observational armillary sphere and a celestial globe; its time-announcing function was enhanced by visual and audible signals. Was this machine primarily a time-keeper or was it only a mechanized astronomical instrument? Such machines existed in Europe, too, before the mechanical clock was established.

Science and technology are the products of the mental and social evolution of mankind. This evolution is certainly a continuous and universal phenomenon; but this does not imply that every culture-area must have undergone the same development in the same period of time or reached the same level of achievement. If we want to understand the inter-cultural transmission of ideas, the first thing is to distinguish between science and technology and between the pre-scientific and the post-scientific stages of technical development. Science is not simply the product of practical work, of technology; nor is technology merely the application of science. Science and technology are separate and independent foundations, historically and in principle. The Chinese never passed beyond the pre-scientific stage of technology; until the Renaissance, however, they were well in advance of Europe in this respect. Post-scientific technology got going in Europe only in the eighteenth century and later; traditional practices prevail even to-day in some industries; and scientific methods are never fully exploited everywhere.

Certainly, the stimuli received from Asia and from mediaeval artisans contributed to the European breakthrough in the Renaissance. Certainly, this breakthrough was not merely a matter of re-reading the classical texts. From the point of view of evolution we have to say that a small group of scientists managed to attain a level of 'abstract' thinking that had not been available previously. It became possible only because European society as a whole managed, to some extent, to throw off religious and other dogmas and to arrive at a more progressive social order. The bureaucratic feudalism of China was not conducive to such a development. If we do not see these differences, we are liable to adopt the attitude of the Chinese gentleman who, when seeing an

aeroplane flying overhead, is reported (in this volume) to have remarked, "Ah, a man in a kite!"

E. H. HUTTEN

INVENTION OF THE CALCULUS

The Mathematical Works of Isaac Newton

Vol. 1. Assembled with an Introduction by Dr. Derek T. Whiteside. (The Sources of Science, No. 3.) Pp. xxi+160. (New York and London: Johnson Reprint Corporation, 1965.) n.p.

VOLUME 1 of *The Mathematical Works of Isaac Newton* is the first of two volumes which the Johnson Reprint Corporation have included in their series "The Sources of Science". It reproduces English translations of three Latin texts on which Newton's reputation as a creative mathematician in the calculus was originally founded. These are prefaced by a useful and scholarly introduction by Dr. Whiteside, who emphasizes that it is "the very depth, complexity, and disorganization" of Newton's mathematical papers which have prevented scholars from producing a satisfactory collected edition.

The first work chosen is the short tract entitled "De Analysi per Æquationes Numero Terminorum Infinitas", written in 1669 but not printed until 1729. The English rendering reprinted dates from 1745—John Stewart's "Sir Isaac Newton's Two Treatises of the Quadrature of Curves, and Analysis by Equations of an Infinite Number of Terms". Here is, as Newton says, "rather shortly explained, than accurately demonstrated" a general method for constructing series expansions of given functions, and then using them by simple integration to solve problems in the quadrature and rectification of curves. John Stewart added a "large Commentary, in which the Demonstrations are supplied where wanting, and the Doctrine illustrated, and the whole accommodated to the Capacities of Beginners for whom it is chiefly designed". The original tract had a restricted circulation but was not printed. Newton, later (1671), added it to an earlier tract on fluxions (October 1666), both subjects being amplified and revised. It was usually known by the title "Methodus Fluxionem et Serierum Infinitarum", and is the second of Newton's tracts to be reproduced, in its anonymous English version of 1737, entitled "A Treatise of the Method of Fluxions and Infinite Series, with its Application to the Geometry of Curve Lines". In spite of its obvious importance, Newton, even after several attempts, failed to find a printer. The third reproduction in this volume is an English translation of a treatise published by Newton in 1704 as a (Latin) appendix to his (English) *Opticks*. This is an article, apparently authorized by Newton, printed in the first scientific dictionary—John Harris's *Lexicon Technicum. Or, an Universal Dictionary of Arts and Sciences (1710)* and entitled: "Quadrature of Curves by Sir Isaac Newton".

The first and third tracts in this volume formed the basis for Newton's claim to priority in the dispute with Leibniz over the invention of the calculus.

The successful introduction of ideas of time and motion for the solution of problems in purely static, timeless, classical geometry was an act wholly alien to Greek thought, and only possible to a mathematical genius of another culture. Newton was, as he tells us, a great admirer of the Greeks, and chose to present the *Principia* in Euclidean form when he could have used an analytical approach. It is interesting, therefore, to note a certain disquiet which he expressed, rather obscurely, when he introduced his method of fluxions: "But since we do not consider the time here, any farther than as it is expounded and measured by an equable local motion; and besides whereas things only of the same kind can be compar'd together, and also their velocities of increase and decrease: therefore in what follows I shall have no regard to time formally consider'd, but shall suppose some one of the quantities propos'd, being of the same kind, to be increas'd by an equable Fluxion, to which the rest may be refer'd, as it were to time; and therefore by way of analogy it may not improperly receive the name of Time. Whenever therefore the word Time, occurs in what follows (which for the sake of perspicuity and distinction I have sometimes used), by that word I would not have it understood as if I meant Time in its formal acceptation, but only that other quantity, by the equable increase or fluxion whereof, Time is expounded and measured" (p. 49).

G. BURNISTON BROWN

STRUCTURE OF THE EARTH'S UPPER ATMOSPHERE

Auroral Phenomena

Experiments and Theory. Edited by Martin Walt. (First Lockheed Research Symposium on Space Science.) Pp. vi+170. (Stanford, California: Stanford University Press; London: Oxford University Press, 1965.) 40s. net.

THE ten papers comprising *Auroral Phenomena: Experiments and Theory* encompass theoretical and experimental aspects of aurorae, with emphasis on the latter. The classical techniques of spectrometry and photometry are represented as well as the sophistication attendant on radar, balloon and satellite experiments.

A most useful contribution by A. Omholt summarizes the proceedings of the symposium, setting out the currently available information and suggesting areas of further work. The notion of the aurora as a small part of a cosmic phenomenon taking place between the Sun and the Earth receives considerable attention, along with a discussion on the effects of bombardment of the upper atmosphere by energetic particles on ionospheric disturbances and atmospheric processes. In any event, auroral activity presents an opportunity to investigate atmospheric structure. One important outcome has been the optical determination of temperature as a function of height in the polar atmosphere. Mention is also made of auroral classification according to the excitation mechanism and the type of particles impinging on the atmosphere, rather than one based on geometry and spectral characteristics of the activity. Although satellites offer intensely interesting studies of auroral morphology, ground observations are by no means obsolete for they still are suitable for examinations of auroral details, in particular rapid pulsations and movements. The television film technique described elsewhere in the volume by T. N. Davis is a truly worth-while step in these investigations as the film can be examined at leisure and particular auroral features inspected quantitatively. The technique is extremely sensitive and an important aspect arising from it is that auroral microstructure researches are possible. An obvious extension of the scheme is to aurora and airglow spectroscopy.

So far as optical measurements of aurorae are concerned, A. Vallance Jones directs attention to the suggestion that whereas synoptic observations of the distribution of auroral emissions can be made with satellite-borne photometers, rocket-borne instrumentation is especially valuable for looking at the height distribution of diffuse auroral forms.

The interactions of energetic charged particles with the atmosphere are discussed by A. Dalgarno. Along with a contribution by J. W. Chamberlain on the present status of auroral theory, this comprises the theoretical content of the volume.

Balloon measurements of X-rays in the auroral zone are described by K. A. Anderson with the classification of X-ray bursts according to their association with geo-

magnetic activity, although it must be realized that such a classification might not be fundamentally related to the mechanisms producing the precipitation. The article by B. J. O'Brien on the precipitation of energetic particles into the atmosphere discusses the observational knowledge on the bombardment of the atmosphere by intense fluxes of charged particles, stressing in conclusion that the problem of the origin of the precipitated electrons is still not solved.

The extensive work on radio studies of the aurora is covered in the contribution by R. L. Leadabrand.

The very promising field of co-ordinated measurements on aurorae, for example the distribution of particle fluxes, optical luminosities, and ionospheric electron densities, is discussed by J. E. Evans. A combination of known techniques on a more intense scale than hitherto envisaged would undoubtedly contribute much towards a complete understanding of auroral processes.

The numerous diagrams are extremely well produced. However, it is unfortunate that no index is included.

A. H. JARRETT

RUSSIAN CLIMATOLOGY

Climates of the U.S.S.R.

By Prof. A. A. Borisov. Edited by Cyril A. Halsted. Translated by R. A. Ledward. Pp. xxi+255+2 plates. (Edinburgh and London: Oliver and Boyd, Ltd., 1965.) 75*s*.

A BOOK which can be read from cover to cover in half a day can be no more than a brief introduction to its subject; with that understanding, and with the further limitation that it covers climatology with little physics and no mathematics, we may welcome a useful translation of Prof. A. A. Borisov's 'educational manual' on *Climates of the U.S.S.R.*

There is an introductory chapter on solar and terrestrial radiation, certainly a good feature; on synoptic climate, tracks of depressions, frequency of air masses, the passage of fronts and so forth, very elementary but worth while; and on the so-called moisture cycle, handled in a way which I found confusing. This first chapter forms a 30-page background for the main part of the book, a pleasant enough mixture of the cartographical, statistical and discursive. The climatic elements for the country as a whole are taken in turn—air and soil temperature, humidity, cloudiness and sunshine, precipitation, evaporation, snow cover—followed by regional notes and statistics for some twenty regions.

Among the better things are the maps showing the climatic regions of the U.S.S.R., according to various classifications, including one following the Köppen system, although the explanations in the text are quite inadequate. The narrative contains miscellaneous information of many kinds providing something new for most readers. For example: "Three quarters of the Asiatic part of the U.S.S.R. is occupied by permanently frozen ground or permafrost" (p. 45); "present low level [of the Caspian] has not been exceeded during the last two centuries" (p. 168); "Barnaul lies within foothills that have become especially dry since the felling of the nearby forests" (p. 205).

The book, now it has been translated into English, will, of course, be examined by everyone remotely interested in the subject, and will be enjoyed unless the dialectic is found too irritating. It is a style not unknown among British geographers and explorers, only quasi-scientific, which often tends to obscurity; but it must be partly the added complication of translation which leads to the following maze: "The most essential factor introducing 'intrazonal' differences consists of macro-meteorological processes, which are characterised not only by their 'dynamism' and areal expression, but also by . . ." (p. 91).

Too many blemishes have indeed escaped the editor, but in providing a good bibliography and an alphabetical list of place-names with almost all their latitudes and longitudes, he has done splendid service. A few places are not so located, but one minor mystery can be resolved from the internal evidence. The highest temperature ever recorded in the U.S.S.R., 50° C, assigned to the unlocated Chu-Adzhi on p. 83, identifies that place with Uch-Adzhi which is twice, on pp. 41 and 179, credited with the like achievement. Is it a case of "what I tell you three times is true"?

R. C. SUTCLIFFE

THE CHALLENGE OF BRITAIN'S CHANGING CLIMATE

The Biological Significance of Climatic Changes in Britain

Edited by C. G. Johnson and L. P. Smith. (Proceedings of a Symposium held at the Royal Geographical Society, London, 29 and 30 October, 1964. Symposia of the Institute of Biology, No. 14.) Pp. x+222. (London: Academic Press, Inc. (London), Ltd.; New York: Academic Press, Inc., 1965. Published for the Institute of Biology.) 42*s*.

AFTER an introductory account of the dimensions of change in the climate of Britain, by H. H. Lamb, *The Biological Significance of Climatic Changes in Britain* is divided into three sections: "The Effects of Climatic Change and their Implications"; "The Manipulation of Materials and Selection of Sites"; and "Perspectives of the Future". Despite variations in quality and aim from paper to paper, the volume is on the whole a stimulating one, though the discussions are often disappointing, sometimes serving simply to underline an unresolved disparity of approach between the contributors from different disciplines.

Two papers on fluctuations in marine communities, one by D. J. Crisp, the other by R. J. H. Beverton and A. J. Lee, are particularly interesting. The first is concerned with inter-tidal molluscs, the second mainly with economically important fish populations. By way of contrast, and lest anyone be tempted to accept simple interpretations of the influence of climatic change on terrestrial productivity, F. L. Milthorpe outlines the many problems posed by any attempt at a quantitative analysis of the relationship between growth or yield and environmental factors. The paper by J. P. Hudson proceeds from a brief practical account of the effect of different types of growing season on different varieties of one and the same crop to a discussion of the potential value of weather forecasts to the farmer or horticulturalist. He emphasizes the value of forecasts 3 to 5 months ahead of the growing season, at the time when crops and particular varieties are being chosen for planting. J. P. Cooper describes what are apparently genecotypic variations in seasonal performance between strains of single forage species, each strain obtained from a different source area. Further appreciation of the physiological and genetic basis for the variations in growth response with source area promises to provide a way of deriving new varieties suitable for special habitats; in the same way, selectively changing biotypes could also help to meet the challenge posed by changes in climate.

After the cautious approach of these and other papers, a return to some of the earlier contributions may come as a mild shock. The interpretation by J. A. Taylor of vegetational changes in parts of Cardiganshire seems very questionable, while his summary of Post-glacial ecological history in upland Wales is also open to serious challenge in the light of recent evidence. The fact is that despite

the elegance with which the experimental biologist demonstrates the subtlety of the relationship between changing environment and plant or animal response, even under the necessarily simplified conditions of his laboratory, most of us are still all too ready both to propose simple climatic explanations for observed biological variations and to rely heavily on evidence from fossil plant and animal remains for quantitative indications of past climatic change. Other lines of evidence, especially for pre-instrumental variations and for very long-term changes, are unfortunately still scarce. However, if it is accepted that we need to know more about long-term climatic variation, and that biological evidence will inevitably contribute to the analysis, then a more critical use of the results in the light of recent work in physiology, experimental taxonomy and genetics is required. In this way, we should perhaps move further away from the dangers of circular argument inherent in so much palaeoclimatology and nearer to providing a factual framework within which the genuinely accurate begins to replace the spuriously precise. Meanwhile, we should take note of the following comment in the paper by Beverton and Lee: "It is deceptively easy to deduce causal connections between two sets of fluctuating data, especially when their reliability and true relationship, if any, are unknown". FRANK OLDFIELD

GEOCHRONOLOGY

Applied Geochronology

By E. I. Hamilton. With a chapter on Comparative Geochemistry by L. H. Ahrens. Pp. xiv+267. (London: Academic Press, Inc. (London), Ltd.; New York: Academic Press, Inc., 1965.) 59*s*.

THE observation of radiogenic argon-40 in potassium-bearing minerals by Aldrich and Nier in 1948 heralded a new era in geochronology. The seventeen brief years which have elapsed since then have seen the establishment of routine analytical techniques for the dating of rocks and their minerals by the potassium–argon, rubidium–strontium and uranium–thorium–lead methods. Progress has been so rapid, in fact, that a considerable gap has appeared between practising geochronologists and the main body of geologists. It was Hamilton's purpose to help bridge this gap with *Applied Geochronology*.

Each major method has a chapter to itself, with the rubidium–strontium and common-lead techniques receiving the most detailed attention. The book opens with a useful, brief chapter on comparative geochemistry by L. H. Ahrens, followed by a historical sketch of the development of geochronology up to 1945.

Chapter 2 is a review of general methods. The techniques of stable isotope dilution and mass spectrometry form the backbone of geochronology and receive detailed description. However, it should be noticed that the two principal equations of isotope dilution are stated incorrectly and there are several minor errors in the account of vacuum technology.

An extensive summary of the various methods of potassium and argon analysis is given. The section on potassium will be found particularly useful. Since the original measurements of Aldrich and Nier, tremendous strides have been taken, and this method is now being used to date rocks in the age range 30 thousand years to 4·5 billion years. Hamilton rightly emphasizes the contribution of Reynolds with his pioneering applications of the ultra-high-vacuum method. This chapter ends with a short discussion of the problems of interpretation of potassium–argon ages obtained on minerals from igneous, metamorphic and sedimentary rocks.

The principles of the potassium–argon method are immediately apparent to the geologist. The rubidium–strontium, uranium–thorium–lead and common-lead approaches, however, are in general not so readily digested, and each one makes a strong appeal to graphical representation. These three topics are dealt with in Chapters 5, 7 and 9 and occupy almost half the book. Until 1958, it had been usual to examine separated minerals with the rubidium–strontium method. Then, in rapid succession, Schreiner in South Africa and Compston and Jeffery in Australia extended their efforts to include samples of whole rocks. It was clearly demonstrated that it is often a risky business to date a rock solely by examination of its separated constituent minerals. Mild tectonic disturbances readily cause the migration of isotopes in and out of minerals to yield anomalous mineral 'ages'. However, in a very large number of cases the average diffusion length is sufficiently small to allow volumes of the whole rock to remain effectively closed systems. Compston and Jeffery emphasized that not only the age of emplacement, but also the initial strontium-87/strontium-86 isotope ratio may be experimentally determined by whole rock analysis. Hamilton devotes much space to a consideration of their graphical representation of whole rock and mineral data. His treatment of this presentation is, however, not so clear as his account of the graphical plot developed by Nicolaysen. The application of the whole rock method to the dating of sediments is discussed and is illustrated by reference to the work on the Hamilton Shales by Whitney and Hurley. Finally, the petrogenetic significance of strontium isotope ratios is illustrated.

The interpretation of uranium–thorium–lead ages is based on the work of Ahrens, Wetherill and Tilton. Ahrens observed that suites of minerals yielding discordant lead ages produced a straight line when their lead-206/uranium-238 ratios were plotted against the corresponding lead-207/uranium-235 values. It was then shown by Wetherill that such a pattern would result if the minerals were all formed simultaneously and remained completely closed systems apart from undergoing a single period of lead loss during their history. He further showed that the two points of intersection of the straight line with the 'concordia' curve gave the times of mineral formation and metamorphism. Tilton then proved that a similar pattern (over a wide range) ensues if, in fact, lead has been continuously diffusing from the crystals throughout their existence. These various arguments are discussed and illustrated with examples from the literature.

Forty pages are devoted to the intricacies of interpretation of common lead isotope abundances. This is a fascinating topic, intimately bound up with the questions of the age of the Earth, the modes of formation of ore bodies, the growth of continents and the uniformity of the mantle. Hamilton reviews the somewhat contrasting theories of Gerling, Holmes and Houtermans, on the one hand, and Alpher and Herman, and Cumming, Russell and Farquhar on the other. One wonders how many geologists will have the persistence to absorb the whole of this chapter. Their way will be somewhat straitened by the errors in some of the equations, but those who make the effort will be amply rewarded by the challenge to sit back and produce their own interpretations.

Applied Geochronology will certainly acquaint the geologist with the tremendous variety of methods available for determining geological ages. Apart from those mentioned in some detail in the foregoing, Hamilton discusses techniques involving carbon-14, rhenium and osmium, ionium and thorium and radiation damage.

The book also contains a wealth of useful references and deals in a pleasing way with work done in the U.S.S.R.

The geological reader, however, will be disconcerted by the imprecise style and the unusually large number of errors. Equations, numerical values of quantities and details of mass spectrometric technique are particularly ill-treated. The book is well produced and bound and the price is reasonable. DEREK YORK

GEOLOGICAL STOCKTAKING IN SCOTLAND

The Geology of Scotland

Edited by Gordon Y. Craig. Pp. xv+556. (Edinburgh and London: Oliver and Boyd, Ltd., 1965.) 105*s*.

IN his preface to *The Geology of Scotland*, the editor gives a short selective history covering the past 150 years, during which this book may be said to have evolved. After mentioning Hutton he refers to Ami Boué's *Essai Géologique sur l'Ecosse* of 1820 and to Nicol's *Guide to the Geology of Scotland* of 1844, an illustrated work with an up-to-date geological map, a revised version of Macculloch's 1836 map. Nicol's publishers then were Oliver and Boyd, who are the publishers now, 120 years later, of the present imposing volume.

However, just a century after Macculloch's death in 1835, a new geology of Scotland, in all but title, was issued in five parts of *British Regional Geology*. These books from the Geological Survey cover all Scotland and present a well-balanced account of the geology accompanied by some candid remarks on the divergent opinions it aroused. Then, at the International Geological Congress in 1948, came an essay entitled "The Structural History of Scotland", by E. B. Bailey (*Intern. Geol. Congress, Report of the XVIII Session*, 230–255; 1950). This summarized progress and views held up to the end of the Second World War. The present volume continues from there, utilizing the results of research carried out during the past two decades involving the routine use of current bedding technique and the geometry of folds, foliation, concepts in metamorphism and deductions drawn from analyses of radioactive isotopes in rock-forming minerals. Some of these exercises require the acceptance and comprehension of more theory than did any of the publications before this epoch.

Prof. Neville George has written an introductory chapter which covers the long period of some 2,600 m.y. between the early Lewisian and the present time. He uses as check points eight tectonic episodes dated by radioactive work. They are as follows: (1) deformation and metamorphism of Lewisian rocks before the Scourie pegmatites *c*. 2,600–2,250 m.y. ago; (2) deformation and metamorphism of Lewisian rocks after the Scourie basic dykes beginning *c*. 1,600 m.y. ago; (3) early metamorphism of the Moines *c*. 740 m.y. ago; (4) Caledonian folding of the Dalradians followed by metamorphism *c*. 440 m.y. ago; (5) later metamorphism of the Moines *c*. 390 m.y. ago; (6) 'main' Caledonian movements including the Moine thrust; (7) 'main' Hercynian movements *c*. 270 m.y. ago; (8) later alpine movements 25–10 m.y. ago.

Some discussion of the column of strata between the check points is given. Scotland is also divided by convenient faults into five geographical blocks, the Southern Uplands, the Midland Valley, the Caledonian Fold-belt with its orderly metamorphic zones split in two by the Great Glen fault, and the Foreland, west of the Moine thrust. Here the Lewisian, traversed by shatter bands of mylonite, is well exposed and here the unmetamorphosed Torridonian west of the thrust can be compared with the Moines east of the thrust, reputed to be their metamorphosed equivalent, carried here from the east by thrusts. The Caledonian Fold-belt is occupied by the Moines and the Dalradian. Although they occur together the latter, probably unconformably, overlies the former. Complex structures affect both groups, but are more difficult to unravel in the monotonous marker-starved Moines than in the Dalradians with their diversified stratigraphy. The folds and over-folds affected by faults are the result of four phases of folding. The whole Fold-belt is pierced by many granitic intrusions and migmatization affects some areas. South of the Highland Boundary fault the Dalradians are covered by the Old Red Sandstone which, further south, rests unconformably on thick packets of shales and greywackes of Ordovician and Silurian ages. These Lower Palaeozoics have been arched up by compression and wrinkled into small asymmetrical folds or faulted folds. In much of the Midland Valley, Carboniferous and Permian lie in open folds. They are much faulted and fill basement-controlled basins. Round the coasts there is a fringe of Mesozoic formations including relics of Cretaceous which with their cover of Tertiary volcanics are also folded and faulted. They show that restlessness continued until late in, if not all through, Alpine time. Towards the end Prof. George allows himself the luxury of 'imaginative reconstruction' in picturing the development of the scenery since a late Tertiary uplift. By then much of the erupted lava and the dykes cutting it had been eroded and a wave-cut surface formed. It was probably warped as it rose. Its crest may have been in the north-west, anywhere beyond the present watershed; possibly so far west as the Outer Hebrides. As rivers gathered and flowed down-slope they produced a group of roughly parallel valleys discharging eastwards. As time went on and tributaries formed they found north-east–south-west fault planes easy to follow and their valleys were eroded more rapidly than those of the primary rivers. In consequence piracy occurred and some of the primary rivers were beheaded to form a network of streams derived from the intersection of the primary and secondary rivers. When the Ice Age came the ice opened and deepened these north-east–south-west fault zones of which the Great Glen is the type and the Minch possibly another example.

The Geology of Scotland is well illustrated, the diagrams clear and instructive. One figure (6.13) may strike a controversial note, as some readers may prefer a section sketched by Sir James Hall in 1812 (Bailey, E. B., *op. cit.*, p. 230) to that by Dr. Walton in 1963 to illustrate Southern Upland structures. The hallowed ground of the Tertiary Volcanic districts, formerly the precinct of J. E. Richey, is described and augmented with an excellent account of recent surveys in Skye and Rum. The volume is, in every way, a worthy member of a long sequence of distinguished works on Scotland. Fashions will doubtless change in the future as they have done in the past and a time will come when another version will be written, say in A.D. 2015 or even A.D. 2065, when more enigmas will have been discussed and left to the future awaiting a final answer.

J. V. HARRISON

THE PHYSICS OF CRYSTALS

Crystal Physics

By G. S. Zhdanov. Translated and edited by Dr. A. F. Brown. Pp. ix+500. (Edinburgh and London: Oliver and Boyd, Ltd., 1965.) 80*s*. net.

CRYSTAL physics has become a branch of science of interest to workers in many disciplines, and as materials, crystals now assume a special importance in technology since they may possess special mechanical, electrical, magnetic or optical properties. The investigation of crystalline media relates the various physical properties of crystalline solids to chemical composition and atomic structure, in addition to covering methods of crystal production and investigating their behaviour and properties over a wide range of physical conditions. *Crystal Physics*, translated from the Russian by Dr. A. F. Brown, of the University of Edinburgh, attempts to give a unified account of this vast subject which will be of interest to all pure and applied scientists with specialist interests in this field.

A knowledge of crystal physics must be based on an understanding of the atomic and electron structure of matter together with the forces of interatomic and intermolecular interaction, and the author has used this as the underlying theme of his book. In the introductory chapters the results of quantum mechanics, which are of particular application in solid-state physics, are estab-

lished and a concise account is given of the structure of the atom and the consequent build-up of the periodic table. There follows a description of the quantum theory of interatomic and intermolecular interactions, and of the basic types of chemical bond. This introductory information is well presented, although much of it may already be familiar to readers of this type of book.

Crystals are introduced by a consideration of the symmetry of atoms, molecules and crystals, and crystal chemistry; the forces of interaction between particles, which lead to the formation of crystals, and the electron theory of crystals, which is fundamental in determining and explaining crystal properties, also receive very adequate treatment. The book concludes with a detailed consideration of the many properties of crystals which are of particular interest in solid-state physics and materials science.

In a work of this type it is inevitable that certain aspects of the subject tend to be omitted, and in *Crystal Physics* this applies to the optical and thin film behaviour of crystals. The book, which is exceptionally well produced, is based on a series of lectures given by Dr. Zhdanov to postgraduate students some ten years ago, and although written primarily for research workers it is unfortunate that few references to original papers are given and that the subject-matter is apt to be out of date regarding the most recent advances in this field.

Problems are given at the end of most chapters and these are solved by the author in an appendix to the book. In view of a shortage of comprehensive books on this topic it should prove extremely useful as a source of information and an introduction to more advanced reading.

D. T. TURNBULL

PLASTIC FLOW AND FRACTURE —A COMPREHENSIVE APPROACH

The Strength, Fracture and Fatigue of Materials

By Takeo Yokobori. Translated by Shigeru Matsuo and Michiko Inoue. Edited by John D. C. Crisp. Pp. 372. (Groningen: P. Noordhoff, Ltd., 1965.) 48.50 D.fl.

THE Strength, Fracture and Fatigue of Metals is a deceptively slim volume, since it contains in its 372 pages the distilled observations and theories of most of the leading workers in the field of fracture during the past 50 years. References are made to more than four hundred authors and a similar number of papers or books on the subject.

In spite of the lapse of 10 years since the original Japanese edition was published, this translation can still fulfil the aims of the author in providing a comprehensive correlation of the many aspects (atomistic, microstructural, macroscopic and statistical) present in the investigation of the problems of yielding, plastic flow, fracture and fatigue.

The early part of the book, after some general considerations including comments on scatter and rate processes, briefly introduces the dislocation theory. Many readers not familiar with this concept might prefer to have this chapter expanded but references give the reader access to original work.

Yielding, the theory of plastic flow, and fracture are next considered in the sequence of their normal occurrence. Some six types of fracture are described and the following chapters deal with four of them—brittle fracture, ductile fracture, fatigue fracture and creep fracture. The section covering creep fracture is limited in extent but in his preface the author promises a further book devoted to that topic.

Nearly half the book is concerned with fatigue. The various stages of fracture are described and later the theories are examined in the light of these observations. Much of this forms a useful critical review, but since the object of the book is to provide a fundamental approach to a much wider subject it is unfortunate that the earlier topics are not so adequately covered.

In collating work from diverse fields there have obviously been problems of reconciliation of the symbols and terms used. In most cases this appears to have been satisfactorily accomplished though some additional definitions at the end might be helpful. In the fatigue section some confusion appears to remain in the use of the terms 'range of stress' and 'amplitude' and also in the condition of 'understress' when related to coaxing.

Some of the correlation from theory to practice appears to be based on limited evidence as presented, but nevertheless it bears out a point made towards the end of the book that "in order to develop the solid state physics . . . in a proper way, it is necessary to give physical and microstructural meanings to the probabilistic factors".

J. F. ALDER

THE FUEL CELL

An Introduction to Fuel Cells

Edited by Keith R. Williams. Pp. xiv+329. (Amsterdam, London and New York: Elsevier Publishing Company, 1966.) 90*s*.

OF recent years, interest in the production of electrical energy by means of fuel cells has been stimulated both by the recognition that we are approaching the limits of efficiency of heat engines in respect to the temperatures permissible in their working parts, and also by the demands for a generator suitable for space research in which financial considerations play but a minor part. This interest has been reflected in the appearance of a large number of articles and a few monographs on various aspects of the subject.

Under the too modest title of *An Introduction to Fuel Cells*, Dr. Williams has presented us with a volume that is remarkable not only for the completeness of the systematic survey of the various types of fuel cells and the theories as to their mode of operation, but also for the clarity of presentation.

The types of fuel cells available are conveniently grouped into those operating at ambient temperatures and under suitable pressure up to 200° C, fused salt electrolyte cells with working temperatures of 350°–800° C, and finally those with high-temperature solid oxide electrolytes. As might be anticipated, cells with aqueous or fused salt electrolytes have received most attention.

From an operational point of view, fuels and oxidants both soluble in the electrolyte are the simplest, and these include such substances as ammonia, hydrazine and methyl alcohol as fuels and hydrogen peroxide or chlorates as oxidants. It is those cells in which gaseous fuels, especially hydrogen and gaseous hydrocarbons, and air as oxidant are used which are of most interest.

It is clear that the conversion of hydrogen to protons at the electrode surface involves a series of steps, any of which may be rate-determining, dependent on the conditions of operation, and the separate factors such as gaseous diffusion, concentration and activation polarization, chemisorption as well as the magnitude of exchange currents are now reasonably well understood, although the picture is by no means complete. On the other hand, our knowledge of the *modus operandi* of the oxygen electrode is far less satisfactory, for the reaction which involves conversion of oxygen into hydroxyl ions is more complex than is the case for hydrogen. It would appear from experiments on catalytic oxidation that surface oxides are first formed; these can be reduced by water, which in turn is converted into hydroxyl ions. Frequently equations involving two electron transfers are used. It seems preferable to regard the transfer as proceeding by steps of single electron transfer, that is, $O^{2-}{}_2 \rightarrow O^{-1}{}_2 +$

$e \rightarrow O_2 + e$; thus permitting the intermediary alternative step $O^{-1}{}_2 \rightarrow O^{-1} + O + e$.

Investigations of the behaviour of both cathode and anode separately under different conditions of operation of the cell have given us a great deal of information on the catalytic properties of different electrode materials on this all-important electron transfer process.

Since hydrogen is relatively expensive compared with the lighter hydrocarbons or carbon monoxide, the most economical cell in fuel costs would utilize methane or a light hydrocarbon or carbon monoxide. The products of combustion of these fuels include carbon dioxide as well as water, and thus restrictions are placed on the type of electrolyte that can be used.

It seems probable that the reactions of the hydrocarbon at the electrode surface involves a series of catalytic steps, a reforming reaction $CH_4 + H_2O \rightleftarrows CO + 3H_2$ followed by the water gas shift reaction $CO + H_2O \rightleftarrows CO_2 + H_2$, the electrode behaving, in fact, as a hydrogen electrode. Both of the foregoing reactions are susceptible to the influence of appropriate catalysts. Again carbon formation may take place, not only by a cracking reaction, for example, $CH_4 \rightarrow C + 2H_2$, but also by the reaction $2CO \rightleftarrows CO_2 + C$. The thermodynamic data on these reactions which form the basis of fuel technology are well established so the most suitable steam fuel ratio to be used at any given temperature is known.

The most desirable electrode evidently should be an effective catalyst for these basic reactions as well as for electron transfer. I have always had an affection for a hypothetical carbon monoxide air cell in which electron transfer is facilitated by the presence of a *p*-type semiconductor. Self-poisoning of the electrode, a phenomenon common to reactions in which intermediary oxidation products may be formed, has to be avoided.

The practical aspects of cell construction involve consideration of porous electrodes, diaphragms, ionic semipermeable membranes and porous fillings for the interelectrode space.

Dr. Williams has included all this material in his book, together with some interesting information on practical cells which have been constructed in the laboratories of several firms as well as a valuable chapter on the economics of fuel cells in general.

The book is well documented. It does not contain many errors. I cannot commend it too highly for those interested in one of the technological challenges of our time, the fuel cell. ERIC RIDEAL

VACUUM TECHNOLOGY IN GERMANY

Vacuum Technique

(Proceedings of a Meeting of the German Society for Vacuum Technique, Heidelberg, September 18–21, 1962.) Pp. vi+94. (London and New York: Pergamon Press, Ltd., 1965.) 70*s*. net.

EDITED by Prof. G. Günterschulze, *Vacuum Technique* is a handsomely produced book which costs ninepence per page of technical information, most of which has been reported elsewhere and, moreover, is published nearly three years after the conference took place. The book contains seventeen papers, three of which are in English and the remainder in German. The practice of holding a conference concerned with a limited number of papers and yet dealing with vacuum technique and its applications in the broad sense is of doubtful value especially when, as in the present case, there is no central theme at all. Such restricted meetings are probably best confined to a special aspect of this very wide field of science and technology. It is even more doubtful whether it is worth publishing the proceedings in full in an expensive book because most readers will only be interested in the detail of one or two of the contributions. However, to indicate to the potential buyer the value of this costly book a summary follows of its contents.

The papers in English comprise an excellent review by Steckelmacher entitled "Methods of Proving the Gas Tightness of Vacuum Equipment and Components", a paper emphasizing the application of ejector pumps by Savini entitled "Pumping Systems for Freeze-drying Plants" and "Sources of Surface Contamination in Vacuum Evaporation Systems" by Holland.

The papers in German commence with a report of the opening address by Klumb on the present state and tendencies in the development of vacuum technique. The following contributions are on the possibilities of the erection of vacuum apparatus from constructional components (Winkler); constructional details and results obtained with a commercial plant for leak-detection of articles by a radioactive technique using krypton-85 (Uhlemann); mass spectrometer investigations of the gas evolution from plastics (Thieme); the significance of negative ions in residual gas analysis (Ahrens); the production of an electrode-less discharge by the use of concentrated microwaves (Geerk, Kleinwächter and Metze); a universal apparatus for the evaporation of electron microscope preparations and optical glasses (Serwatzky); limitations to the use of vacuum in the preparation of insulating oils for electro-technology (Stoll); the industrial measurement and regulation of vacuum (Schink); the production of microwave tubes by the use of getter-ion pumps (Stolz); metallization in high vacuum of bands of material with special regard to pre- and post-handling (Berisch); a new arrangement for the production of thermal gas streams and the measurement of radiometer forces (Krupp, Robens, Sandstede and Walter); measurement of the sorption, evaporation and decomposition of vacuum materials with an electromagnetic microbalance (Robens, E., Robens, G., and Sandstede); and the application of permanent magnets in vacuum technique (Brinkmann). J. YARWOOD

A LAYMAN'S GUIDE TO THE ATOM

Explaining the Atom

By Prof. Selig Hecht. New edition, with revisions and additional material by Dr. Eugene Rabinowitch. Pp. xviii+237. (London: Victor Gollancz, Ltd., 1965.) 18*s*. net.

"THIS book is for the complete layman", wrote the American author in 1946 as he moulded into book form five lectures for an audience most of whom had had no training in science. Three atomic bombs had been exploded and the Smyth report had been published; Congress had passed a Bill providing the death penalty for giving away the secret of the atomic bomb. Prof. Hecht set out, with very many other scientists, to dissipate ignorance and inform the public of the elementary principles relating to the release of atomic energy and, as Prof. Rabinowitch writes in the foreword to the revised edition of *Explaining the Atom*, he "brought to the campaign his unique gift for clear, simple, and convincing exposition of science".

The result is a most readable book which went into many printings in the United States; it deals briefly with the whole story of the development of atomic theory from the days of Dalton to the end of the nineteenth century when the electron emerged from the 'solid' atom, and then continues with descriptions of the salient experiments from which nuclear theory evolved.

This story has been told, of course, in many British books for the layman and for junior readers, and Hecht's book adds nothing except eminent readability. He seems rather surprised at the excitement created among physi-

cists by the announcement of the discovery by Hahn and Strassman of fission and Miss Meitner's explanation thereof, but the discovery came after four years of searching for the explanation of Fermi's transuranic elements and during that time not one of the great captains of physics, neither Bohr, nor Rutherford, nor others, had even considered the possibility of fission and the great release of energy which must accompany such disintegration. Those who lived through that period will never forget the intense excitement and speculation which occurred almost within days of the news; bombs and power stations at last appeared technically possible. This Hecht explains.

The author died in 1947 and Prof. Rabinowitch revised the book in 1954, recounting again the sad story of the attempts to establish international control of atomic weapons, and also describes the fusion of hydrogen into helium and its application in 'super-bombs'. Although *Explaining the Atom* has had some further revision, the peaceful applications of atomic energy are not adequately dealt with and there is little to indicate the vast strides which have been made in the past decade.

The illustrations do not match up to the excellent presentation of the facts. There are too few, some are drawn with errors, and when reference is made to them in the text, the page reference is not given so time is wasted searching for the appropriate illustration.

T. E. ALLIBONE

REDOX POLYMERS

Oxidation-Reduction Polymers

(Redox Polymers). By Harold G. Cassidy and Kenneth A. Kun. (Polymer Reviews, Vol. 11.) Pp. xv+307. (New York and London: Interscience Publishers, a Division of John Wiley and Sons, 1965.) 95*s*.

OXIDATION-Reduction Polymers, the most recent addition to the well-known "Polymer Reviews" series of books dealing with individual topics in polymer science, is concerned with a relatively new polymer type containing chemical groupings which participate in electron exchange phenomena.

After a brief general review of the field, the synthesis of these polymers is discussed. The two major approaches are considered separately, namely the polymerization of a suitable monomer which contains appropriate redox groups or the chemical attachment of redox groups on a preformed polymer. To the former approach there are many obstacles, since the redox centres may be expected to interfere with the free radical, ionic or condensation polymerization. Individual examples are discussed in detail and techniques for blocking reactive groupings described so that the polymerizations are unaffected by inhibition or transfer reactions. The second approach of modifying a prepared polymer may be achieved by precipitating or adsorbing the redox material in an inert matrix, or by chemically bonding it to the polymer backbone.

The succeeding chapter gives a concise account of oxidation-reduction theory and the setting up of electrochemical cells for the measurement of electrode potentials. The special problems associated with insoluble redox resins are dealt with and also the use of mediators to overcome them. Typical titration curves for single substances and for mixtures are described and their interpretation discussed in detail.

The largest chapter in the book concerns the measurement of the properties of redox polymers. The principal difficulties of measurement are connected with the high molecular weight and hence relative insolubility of these systems. There is no discussion of the measurement of the usual polymer properties, the main interest lying in the electrical properties and microstructure. The apparatus used for carrying out potentiometric titrations is described in detail, together with that necessary for the control of ambient conditions. In this connexion, it is of the utmost importance that reagents and solvents should be prepared in a standard way, and special difficulties arise since non-aqueous media must on occasion be used. It is also necessary to be able to define the micro properties of these polymers in terms of surface area, pore size, pore size distribution and pore structure, and here a number of conventional techniques with appropriate modifications can be applied. The measurement of redox capacity of a resin is also dealt with.

The properties of individual redox polymers are dealt with in a classified chapter in which polymers are separated according to mode of preparation, solubility and composition of the functional groups. The physical, optical and electrical properties are detailed and discussed in the light of the general theories elaborated earlier in the book.

The final section of the book deals with the applications of oxidation-reduction polymers in ion-exchange; in utilizing the self-buffering action of appropriate copolymers; as catalysts for the formation of hydrogen peroxide; for the de-oxygenation of water and reduction of boiler corrosion; for water purification and waste disposal as well as more specialized uses in biological studies; chemotherapy; photography; electric battery construction and as a dielectric. The authors also speculate on further uses of these substances.

In addition to the references which are provided for each chapter, there is an extensive annual bibliography dealing with not only works and articles but also patent applications. These references are also annotated in such a way as to provide a better indication of the content of individual items. The book is well illustrated where appropriate with diagrams and figures.

This specialized text will appeal to anyone engaged in the study of redox polymers and to those in the general field of polymerization who wish to get a clear, concise account of the special properties of these substances. As a source-book it will find much use by those who wish to extend present understanding and use of oxidation-reduction polymers.

JAMES C. ROBB

AERODYNAMIC AESTHETICS

Theory of Optimum Aerodynamic Shapes

Extremal Problems in the Aerodynamics of Supersonic, Hypersonic, and Free-Molecular Flows. Edited by Prof. Angelo Miele. (Applied Mathematics and Mechanics: An International Series of Monographs, Vol. 9.) Pp. xix+455. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1965.) 132*s*.

APPLIED mathematicians approach their work in different ways. One way is to master and develop a particular mathematical technique and then apply it to as many physical problems as possible. Prof. Angelo Miele has followed this path with distinction; he is an authority on variational methods which he has applied to an extremely wide range of optimization problems in the fields of aerodynamics, flight mechanics and astronautics.

In *Theory of Optimum Aerodynamic Shapes* Prof. Miele restricts his attention to the determination of the external shape of bodies, subject to various geometrical constraints, giving minimum drag in certain flight régimes. At supersonic speeds optimum shapes of two-dimensional wings and bodies of revolution are discussed on the basis of linear and second-order aerodynamic theories, taking into account skin friction effects; optimum shapes for rocket nozzles are also described. At hypersonic speeds similar problems are solved assuming first the Newtonian pressure law and then the Newton–Busemann pressure law. A short section is concerned with the optimum-shaped body of revolution in free molecular flow.

The presentation of all this information is somewhat unorthodox. As an introduction, the first four chapters

are devoted to a lucid and rigorous review of the elements of the calculus of variations. The remainder of the book is a collection of twenty-five important papers published in recent years; about half these papers are by Prof. Miele and his associates, the rest are by well-known authors including R. T. Jones, C. Ferrari, G. V. R. Rao, K. G. Guderley, W. D. Hayes, A. J. Eggers and G. G. Chernyi. All the papers, each designated as a separate chapter, have been extensively edited to ensure uniformity of formulation, standardization of notation and consistency of style—a creditable achievement.

Unfortunately groups of these papers are so closely related in content that for each paper to be treated separately leads to a mathematical sameness and an extremely slow development of the main points of interest. For example, six chapters, or papers, are concerned with the determination of the optimum shapes of bodies of revolution in Newtonian hypersonic flow; different initial assumptions are made in each case: slenderness is first assumed without skin friction, then with constant skin friction coefficient, then with variable skin friction coefficient and then the exercise is essentially repeated for non-slender bodies. There is insufficient mathematical difference between these various aspects to warrant separate chapters. From a practical point of view each chapter in this sub-group is made obsolete by the slightly more generality of the following chapter. The ultimate disillusionment comes in the next section in the book where it is established that bodies with non-circular cross-sections can have lower drags than optimum bodies of revolution. Some discussion of the philosophy of the formulation of optimal problems would have been welcome.

This final point leads on to a further comment. Only those problems are discussed which can be formulated within the framework of the calculus of variations. Thus the brilliant concept of the Busemann supersonic biplane is not mentioned. Neither is there any reference to the vast volume of literature on the transonic and supersonic 'area' rule techniques for minimizing drag of wing-body combinations. It might be argued by Prof. Miele that his terms of reference are not intended to cover such topics, but nevertheless the title of the book does suggest considerable generality.

In conclusion, recognizing the book as a text on the calculus of variations with some applications to the determination of optimum aerodynamic shapes, it is a valuable contribution to aeronautical literature. But it is not so comprehensive as the title implies. In my opinion it could have been condensed with, one hopes, a corresponding reduction in price. G. J. HANCOCK

OPERATORS AND TRANSFORMS

The Dynamics of Linear and Non-Linear Systems

By P. Naslin. Translated from the French. Pp. xxvii+586. (London and Glasgow: Blackie and Son, Ltd., 1965.) 105*s*. net.

IT is now many years since Gustav Doetch showed that the Heaviside operational calculus could be given formal justification in terms of the Laplace transform, which is now accepted as the appropriate tool for solving problems concerning linear systems set in motion at $t = 0$, the subsequent history of which is to be determined. As such it now features in the curriculum of almost all engineering courses of degree or comparable standard.

It therefore seems a pity that the author of *The Dynamics of Linear and Non-Linear Systems* relegates it to a brief appendix. At one place he objects that it involves initial conditions, at another that it is too powerful a tool for the job to be done.

When an input and an output function are connected by a linear differential equation with constant coefficients he replaces d/dt by p and expresses the ratio output to input as a rational function of p which he calls the transmittance. It includes both impedances and admittances when the quantities are electrical.

In a note on the symbols s and p he says that s has the specific meaning of the complex variable of Laplace transform theory, whereas p simply stands for the operator d/dt and thus has a purely symbolic value. The author is right that the transmittance is not a Laplace transform, but it seems just as much a misuse of terms to call it, as he does, a 'p-transform'. Equally to regard p as meaning simply d/dt is absurd when the poles and zeros of a transmittance are considered.

The only logical point of view is that the transmittance is the transmission ratio when the input and output depend on time through the exponential factor exp pt. This justifies at once replacing d/dt by p and the differential equation may be recovered by reversing the steps. The steady-state transmission ratio is obtained by setting $p = j\omega$, and, replacing p by s or not, the transmittance function coincides with the Laplace transform of the output when the input is a unit impulse.

Linear systems are represented by block diagrams. Thus if a battery e.m.f., E, is the input to a simple potential divider with resistances R_1 and R_2 in series, the output being the potential v across R_2, this is represented by applying E through an adder to a multiplier $1/R_1$ which produces the current i. This applied to a second multiplier R_2 gives v, while a feed-back path with multiplier -1 runs from v back to the adder so that $E-v$ is actually applied to the first multiplier.

Instead of multipliers there may be integrators, differentiators or more complicated systems. The block diagram may be modified in a variety of ways without altering its overall transmittance. It may be arranged so that only adders, multipliers and integrators are used when it gives the lay-out for an analogue computer simulation of the system. Its use is illustrated in a variety of examples always with application to control systems in mind. The block diagram is easily converted to a signal flow graph for which Mason's formula expresses the transmittance in terms of the transmittances of open paths and closed loops on the graph.

Transients and the sinusoidal steady-state are discussed very thoroughly in close relation to each other and to stability and damping. There is a short chapter on sampled data systems.

The later chapters treat non-linear systems but the emphasis is still on situations where linear theory can be applied: first, the so-called describing function procedure when the effects of harmonics above the first may be neglected, and secondly, phase plane methods applied mainly to problems in which different linear approximations may be used in different ranges of the variables.

In this part of the book some of the figures are not so accurate as they purport to be, possibly through being copied by a draughtsman unfamiliar with the problems represented. The layout of the text and figures is attractive, but for a rather large number of trivial printing errors such as a symbol missing from a formula.

In one respect there is a curiously old-fashioned air about this book. Laborious step-by-step graphical and tabular solutions are described, sometimes with the comment that all the calculations were done on a slide rule. Surely, in these days, every design office concerned with this type of problem has a digital computer available, and some work on numerical analysis features in all engineering courses so that it should scarcely be necessary to devote a final chapter to describing the simplest Euler and modified Euler methods of solving differential equations.

Despite its faults, this book contains a lot of useful and interesting material particularly relevant to the design of control systems. A. W. GILLIES

LECTURE NOTE VOLUMES

Brandeis Summer Institute in Theoretical Physics

Vol. 1: Lectures on Strong and Electromagnetic Interactions. By P. T. Matthews, D. R. Yennie and M. E. Mayer. Pp. iii+343. 24*s*. Vol. 2: Lectures on Astrophysics and Weak Interactions. By S. Hayakawa, H. Y. Chiu, G. Feinberg and M. Dresden. Pp. v+471. 32*s*. 6*d*. (Waltham, Mass.: Brandeis University. Distributed by Gordon and Breach, New York, and Blackie and Son, London, 1964.)

IN the quickly developing areas of science, such as those to which *Lectures on Strong and Electromagnetic Interactions* and *Lectures on Astrophysics and Weak Interactions* offer contributions, the pressure for shorter and shorter publication times for more and more material has extended from the research journals to the text-books; hence the spate of 'lecture note volumes', as they are called. Notes of lectures at the various summer schools are written up either by the lecturer himself, or more commonly by a student attending the school, and published as quickly as possible, usually in paper-back and usually with a minimal amount of editing. Their purpose must be considered primarily didactic. As the editor of the volumes reviewed here claims, "These notes should provide a valuable introduction to areas of contemporary research interest".

A "valuable introduction" for whom? All three articles of Volume 1 would make little sense to a reader without at least some familiarity with the ideas of elementary quantum field theory. Given this background, the notes of the lectures by Matthews provide a readable introduction to the S-matrix and its uses in strong interaction physics. There are also useful sections on applications to low-energy π–N and $\bar{K}$–N scattering, the determination of the quantum numbers of resonances and high-energy scattering. I am not so confident of the usefulness of the notes of the lectures by Meyer, which purport to be an introduction to the SU_3 symmetry scheme of strongly interacting particles. The lectures seem to have been a review very much for the experts; terms such as "Weyl's branching theorem", "Casimir operator", "Okubo's form for the mass matrix" are bandied about without being adequately explained. More readable introductions to the SU_3 scheme now exist in print which cover essentially the same material. Yennie's article is perhaps more specialized and detailed than the other two articles of Volume 1, but certainly no less readable, nor requiring any more background knowledge. It gives an exposition of the techniques associated with the author's name for making the Lamb shift calculations, and an account of the treatment of the infra-red divergence problem and radiative corrections to high-energy scattering.

There are even more variations in the assumed background knowledge of the readers of the various contributions to Volume 2. The title of the lecture notes of Chiu, "Neutrino Astrophysics", is a little misleading. They are divided into two parts and only the second deals at all with neutrino processes, stellar collapse and neutron stars. I can recommend the first part as a very readable brief introduction to the ideas of astrophysicists on stellar sizes, stellar structure, nuclear reactions in stars and stellar evolution. Much of the material requires as background no more than an honours degree course in physics. The other astrophysics article, by Hayakawa on "The Origin of Cosmic Rays", precedes that of Chiu in the volume. However, it would not be intelligible to anyone who has not already a fair familiarity with the ideas presented in Chiu's article. The other two articles in Volume 2 are for specialists in elementary particle physics. That of Feinberg is largely on the intermediate vector boson theory of weak interaction processes, its field theoretic formulation, and possible effects of higher order graphs. The article of Dresden is a very complete and carefully written account of theoretical speculations on the possible existence of particles obeying neither Bose–Einstein nor Fermi–Dirac statistics.

One might well question the wisdom of the continuing publication of these lecture note volumes. They are not books. For, in the interests of speed, there is no attempt on the part of the editor to make uniformity either in lay-out or notation or even in method of referencing. In the second volume even the ordering of the articles seems inappropriate. In all but two cases, the lecturers did not even write their own contributions. In the foreword the editor points out that two of the lecturers "generously devoted time to reviewing the work of their notetakers, but have not undertaken extensive revisions". It seems to me a question not of the generosity of the lecturer but of his responsibility to ensure that whatever is published under his name is as accurately as possible what he wants to say. The editor says that "the notes are intended to be informal presentations, not formal monographs". But the informality of a presentation certainly does not add to its clarity, if it entails, as it seems so often to do in these volumes, undefined notation, carelessly stated principles and badly labelled diagrams. In spite of it all, some things come through and some of the articles will be useful to some people.

J. E. PATON

SPECIAL CERAMICS

Special Ceramics 1964

Edited by P. Popper. (Proceedings of a Symposium held by the British Ceramic Research Association.) Pp. xii+341. (London: Academic Press, Inc. (London), Ltd.; New York: Academic Press, Inc., 1965. Published for the British Ceramic Research Association.) 90*s*.

THE term ceramics, be they special or not, includes a vast range of solid materials. In the past few years the definition, which originally included only materials based on clay, has been widened progressively so that we now readily accept such statements as "In materials there exist some that are neither metals nor elements nor polymers, these are ceramics". *Special Ceramics 1964* indicates that even this is not wide enough and 'polymers' must be limited to purely organic polymers, since we find included three papers dealing with inorganic polymers. There are twenty-two papers in all and, with the vast range of topics available, it is scarcely surprising that they are as heterogeneous as some of the materials they describe. Although the majority of authors are British, there are also contributions from continental Europe, the United States and Australia. Generally speaking, this is not a book for the theoretician, but rather for the practical scientist who wants to know how to make things, how and where to apply them, what their important properties are, and how to measure them.

Topics are divided roughly into six sections: preparation of non-oxides; pyrolytics and inorganic polymers; oxides; properties; fabrication techniques; and applications. The first section has one paper on the preparation of new high-temperature materials for atomic energy usage, another in which modern theory is applied to an old sintering problem, and the third is a structure analysis of zirconium oxycarbides. The first two of the second group of papers deal with the technologically very interesting formation of hard, impervious, inert layers of silicon carbide on various substrates. The second paper, on inorganic polymers, contains much introductory and background information and, I feel, could well have come first in the section. The other two deal with the preparation of specific polymers. The four papers in the oxide group consist of one on the preparation of high-purity powders, another on the problem of alumina analysis, a third on the improvement of high-temperature structural material by metal infiltration,

and a final paper on preparation and properties of spinel. There are five papers dealing with properties. Three concern electrical properties. Under electrical stress, especially at elevated temperatures, ions from electrodes and from the ceramic material itself migrate, causing rapid degradation of electrical characteristics. This important commercial topic is dealt with at length. The other two papers are concerned with thermal conductivity and friction characteristics of some special compounds. Of the three fabrication papers, two discuss hot-pressing techniques, and the third electron beam melting. In two papers on applications, emphasis is placed on the use of ceramics in high-performance gas-turbine and jet engines.

Most of the papers are short and the inclusion of numerous photographs, figures, graphs and good abstracts makes for easy reading. The British Ceramic Research Association is to be congratulated for producing this useful book, and for playing their full part in leading ceramics out of the empirical wilderness. J. H. MANNING

CHEMISTRY OF NATURAL PRODUCTS

Recent Developments in the Chemistry of Natural Carbon Compounds

Vol. 1. Edited by R. Bognár, V. Bruckner and G. Fodor. Pp. 319. (Budapest: Akadémiai Kiadó, Publishing House of the Hungarian Academy of Sciences, 1965.) 14.70 dollars.

THE Chemical Department of the Hungarian Academy of Sciences has set itself the task of publishing a series of monographs on natural products, dealing mainly with the elucidation of structures. It is claimed as an individual feature of the series that it will collect for the first time relevant work of Hungarian chemists and offer to the English-speaking reader material that may only have been accessible previously with difficulty.

Recent Developments in the Chemistry of Natural Carbon Compounds, the first volume in the series, comprises three monographs by distinguished authors. About half the book (146 pp.) is taken up by a very detailed, lively and critical review by G. Fodor entitled "New Methods and Recent Developments of the Stereochemistry of Ephedrine, Pyrrolizidine, Granatane and Tropane Alkaloids". The major part of this monograph concerns, of course, the tropane alkaloids which have been so thoroughly investigated by Fodor and his collaborators, who have published much of their work in the *Journal of the Chemical Society*. The second monograph (70 pp.), entitled "Relationships between the Structure and Pharmacological Activity of Tropeines", by K. Nádor, continues the alkaloidal theme and is complementary in a sense to that of Fodor. It discusses parasympatholytic, ganglion-blocking, and local anaesthetic activities of tropeines, and the curare activity of *bis*-quaternary tropeines; biological activities relative to those of standard compounds are given in convenient tabular form. The third monograph (85 pp.) entitled "Achievements in the Total Synthesis of Natural Steroids", by the Russian author, I. V. Torgov, is a more general and objective review of the methods that have been developed for the total synthesis of steroids. All the important routes are discussed in logical order, but, as there have been no Hungarian contributions to this field which is already well known to English-speaking readers, the reason for the inclusion of this admirably succinct contribution in the present volume is not clear.

The book is well produced and the standard of the English is quite high, but it suffers from two defects. In the first place, though published as recently as 1965, the three monographs would appear to have been written about 1960 and such references as are given to later work appear as footnotes. Secondly, the analytical contents list at the beginning of the book is scarcely adequate to serve as an index to the very considerable amount of factual information contained between its covers. In spite of these minor shortcomings the book can be recommended for stimulating accounts of the three selected topics. J. WALKER

VALENCE THEORY

Valence Theory

By Prof. J. N. Murrell, S. F. A. Kettle and Prof. J. M. Tedder. Pp. xiii+401. (London and New York: John Wiley and Sons, 1965.) 50*s*.

DURING the past thirty years, many, many books have been written on the subject of valence theory and its quantum mechanical basis. Some set out to explain the basic theoretical methods and to show how wave functions may be determined and used. Others aim to give a qualitative picture of the results of quantum mechanics as applied to molecular structure and to consider the application of these to a wide range of actual molecular examples. Because of the dangers of falling between two stools, it is particularly essential in this field for an author or authors to have a clear idea of who they are writing for. There are so many alternative approaches and needs that to attempt all may easily be to achieve nothing.

One great difficulty is, of course, that there are many chemists who need to have as good a grasp as possible of the ideas and results of quantum mechanics but who, because of the many other things they must learn, have only limited, and usually it must be accepted, rather inadequate, time to devote to it. Different teachers of valence theory would take different views as to how much it is reasonable to expect such experimental chemists to assimilate and how best to avoid the dangers of partial knowledge and limited understanding, but none, I think, would deny the greatness of the problem.

Murrell, Kettle and Tedder have in fact set themselves the very difficult task of trying to bridge the gap between the two types of approach as illustrated by those excellent books *Valence*, by C. A. Coulson, in which the approach is semi-qualitative, and Eyring, Walter and Kimball's more formal *Quantum Chemistry*. They have produced a book which will be valuable to experimental and semi-theoretical chemists, whether they are interested in inorganic or in organic chemistry. There is a short introductory section dealing with such topics as the hydrogen atom and basic principles of valence theory. There follow a few chapters dealing with the mathematical foundation, symmetry and angular momentum. By this stage we are about one-third of the way through the book. Next there come chapters dealing with molecular orbital and valence bond theory, first in diatomic and then in polyatomic molecules. More specialized chapters follow which are devoted to ligand field theory, electron-deficient molecules, π-electron theory, induction, hyperconjugation, reactions in organic chemistry and weak chemical bonds. *Valence Theory* is written to be used by university students, and problems are included throughout; useful hints on their solution are given at the end of the book together with answers.

The material is presented clearly and the printing of formulae, tables and diagrams is of a high standard. The only worry I have is that, in attempting to 'fill in the gap', the authors have at times involved themselves in fairly sudden changes in the difficulty of the material presented. For example, there are many who will find the change from the chapter entitled "Basic Principles" to the one entitled "Mathematical Foundations" quite

difficult to manage. It is to be hoped that they will not be scared into proceeding no further; this would be a pity because such readers will find, if they go on, that later chapters are very useful indeed.

One could not say, with all honesty, that one welcomed all the books that had been written on valence theory, quantum theory for chemists, etc. However, with *Valence Theory*, it is possible to say with sincerity that it is a most welcome book. It provides a reasonable coverage in a reasonable space starting with the elements of the subject and proceeding well on into the more difficult parts. It does this clearly and is well produced. The authors must be congratulated on producing a book which has so much of value in it and which is so well suited to the needs of chemistry students in many British and other universities.

J. W. LINNETT

ASPECTS OF POLYMER CHEMISTRY

Analysis and Fractionation of Polymers

Edited by John Mitchell, jun., and Fred W. Billmeyer, jun. (American Chemical Society Symposia held at Chicago, September 2–3, 1964. *Journal of Polymer Science*, Part C, Polymer Symposia, No. 8.) Pp. vi+314. (New York: Interscience Publishers, a Division of John Wiley and Sons, Inc., 1965.) 96*s*.

ANALYSIS and Fractionation of Polymers contains papers presented at symposia on "Analysis of High Polymers" and "Characterization and Fractionation of Polymers", held at the American Chemical Society meeting in Chicago in September 1964. Some of the papers are written in general form and may be regarded as being in the nature of reviews; other papers are devoted to new information on specific polymer systems. Pyrolysis gives information on polymer composition as well as on kinetics of polymer degradation, and the first group of papers describe pyrolytic techniques, with emphasis on methods of detection of products. This is followed by a description of the use of high-resolution differential thermal analysis and the new technique of dynamic electro-thermal analysis. The next series of papers is devoted to recent applications of infra-red spectroscopy and, in particular, to fluorine-containing polymers and polyacrolein. Other papers describe the use of tritium or carbon-14, and viscosity methods in the study of polyacrolein. The application of high-resolution nuclear magnetic resonance spectroscopy to the investigation of fluorine-containing polymers, polypropylenes and relaxation phenomena are described in detail in succeeding papers.

The second half of the volume is devoted to the topic of the fractionation of polymers and their characterization in terms of molecular weight. The first two papers on molecular weight distribution and methods of fractionation provide valuable and up-to-date reviews of these subjects. The following papers deal with different aspects of solution-gradient electron fractionation and the theory, practice and instruments for gel-permeation chromatography. The remaining papers cover various topics such as the interpretation of molecular weight distribution data, the bulk fractionation of linear polyethylene, the determination of molecular weight distribution by sedimentation velocity, ultracentrifugation and the use of light-scattering techniques.

The papers not only summarize 'the state of the art' regarding the more familiar methods but also describe some of the newer techniques of analysis, characterization and fractionation. The volume will be of considerable interest and usefulness to those interested in these subjects.

C. E. H. BAWN

LIGNIN BIOCHEMISTRY

Lignin Biochemistry

By Walter J. Schubert. Pp. ix+131. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1965.) 8 dollars.

NATURE has defied chemists in their attempts to write a single structural formula for the lignin molecule, and present-day ideas on the structure are usually related to a 'statistical' model incorporating a variety of phenyl-propane derived units linked together in different ways to take account of the known analytical data. The pulp and paper industries have been even less successful in their efforts to find profitable outlets for the vast quantities of lignin-derived waste which at present only represents an often embarrassingly large disposal problem. The microbiological utilization of lignin and its derivatives would appear to be a worth-while field of study for both chemists interested in lignin structure and for industries faced with the problem of its disposal. However, to date, such research has provided little other than corroborative information on lignin structure and no practical help to engineers concerned with the disposal of pulping wastes.

Dr. Schubert and his colleagues have been studying the biosynthesis and the fungal degradation of lignin for several years and *Lignin Biochemistry* is based largely on the work of the Fordham University school.

The book is arranged in four chapters. Chapter 1, occupying approximately one-third of the book, deals with the chemistry of lignin, a knowledge of which is essential to an understanding of its biosynthesis and degradation. The field is covered quite comprehensively and some of the more valuable techniques and many of the difficulties facing the lignin chemist are described.

Chapter 2 discusses aromatization in micro-organisms and is a much less full treatment of the subject than that given to the chemistry of lignin. The shikimic acid pathway in bacteria is briefly dealt with and its application to the biosynthesis of tyrosine and phenylalanine described. The biosynthesis of aromatic metabolites by wood-destroying fungi is then discussed in detail. However, the significance of this to the aromatization process in plants and to lignin biosynthesis is not obvious and could have been dealt with much more briefly.

The biosynthesis of lignin in plants is covered in Chapter 3. Tracer studies have established the biosynthetic routes to the lignin 'building stones' but the final stage in lignin synthesis, the polymerization of these precursors within the plant cell wall, is still a matter for conjecture. Freudenberg's hypothesis that soft-wood lignin is synthesized from coniferyl alcohol by dehydrogenation and free radical polymerization is discussed and its limitations pointed out.

The final chapter deals with the microbiological degradation of lignin. The emphasis is very much on the part played in the lignin cycle by wood-destroying fungi, other organisms being almost entirely ignored. Lignin degradation by these fungi is considered to be an oxidative process and the difference between laccase and phenolase, the two commonest oxidative enzymes associated with these fungi, is clearly described. However, while the importance of laccase and phenolase in the classification of wood-destroying fungi is emphasized, their over-riding importance in lignin degradation has yet to be established, a point which is not so clearly brought out.

The book is very well produced, but at 8 dollars for 111 pages of text and eight of references, it is expensive and the cost may well limit its appeal. To the non-specialist it offers an introduction in some depth to a complex subject but the specialist reader may find that as a review it suffers from being too personal an account with a consequent imbalance and incompleteness in places.

N. J. KING

DIAZONIUM AND KINDRED ORGANIC COMPOUNDS

Methoden der Organischen Chemie

Von Houben/Weyl. Vierte völlig neu gestaltete Auflage. Herausgegeben von Eugen Müller. Band 10, Teil 3: Stickstoffverbindungen, 1/3. Herausgegeben von Rudolf Stroh. Pp. xliii+971. (Stuttgart: Georg Thieme Verlag, 1965.) 255 D.M.

IN the new edition of *Methoden der Organischen Chemie*, two volumes, 10 and 11, are devoted to the preparation and reactions of organic nitrogen compounds. The work reviewed here is Part 3 of Volume 10, and its publication has preceded that of Parts 1 and 2 of this volume. Parts 1 and 2 of Volume 11 have already appeared: Part 1 deals solely with amines and Part 2 with alkylinimines, amino-acids, lactams, quaternary ammonium salts, and nitrogen–sulphur compounds.

Part 3 of Volume 10 is a substantial work of 971 pages, of which almost the first half is devoted to the two most important chapters, namely, those on aromatic diazonium salts (212 pp.) and on diarylazo compounds (254 pp.) respectively. The first chapter deals in detail with the preparation of diazonium salts from amines by diazotization under various conditions, according to the nature of the amine used, and by other methods such as oxidation of aromatic hydrazines or reduction of aryl nitramines: a short section deals with the diazotization of heterocyclic amines. The second part of the chapter deals with the reactions of diazonium salts with a large number of reagents under a variety of conditions and thus illustrates fully their synthetic applications, other than those discussed later in the book.

The second chapter, on diarylazo compounds, describes the formation of these compounds by the coupling of diazonium salts again with a wide variety of compounds, with the special conditions which the nature and position of substituents in these compounds may make necessary. Other reactions are surveyed, and a very interesting discussion is given of the types of complexes which diarylazo compounds, with suitable substituents to form chelating groups, may form with metallic salts, particularly with those of chromium, cobalt and nickel.

This very concise summary of these two important chapters cannot do justice to their contents. It must be emphasized that in this volume, as in others in the series, an exhaustive and up-to-date account is given of almost all recorded synthetic methods, both of the main compounds and the products to which they can give rise, and this account includes experimental details for various typical preparations, and tables listing the known examples of the compounds prepared by particular reactions, the whole accompanied by a wealth of references. Each of these two chapters could well be published as a separate book, and each would be of considerable value to the organic chemist.

Other shorter sections deal with aromatic–aliphatic azo- and azoxy-compounds, aryl hydrazones, formazanes, aromatic triazenes and higher azo homologues, aromatic azoxy compounds, organic azido compounds, and nitrile oxides.

It is noteworthy that in this volume, as in earlier ones, the potentially dangerous nature of a compound is emphasized, as in "Das (*cancerogene*) β-Naphthylamine".

This volume will be invaluable to chemists engaged mainly in synthetic work involving aromatic nitrogen compounds, and will be of particular interest to those in the dyestuffs industry.

The excellent presentation and printing of the text are of the same very high standard as that of earlier volumes.

F. G. MANN

PROTEINS AND THE ALIMENTARY TRACT

The Role of the Gastrointestinal Tract in Protein Metabolism

Edited by H. N. Munro. (A Symposium organized by the Council for International Organizations of Medical Sciences, established under the joint auspices of UNESCO and WHO.) Pp. xviii+402. (Oxford: Blackwell Scientific Publications, 1964.) 75*s*. net.

THE Role of the Gastrointestinal Tract in Protein Metabolism presents the twenty-five papers delivered at a three-day international symposium held in Glasgow in August 1963. The objective of the meeting was "to provide a comprehensive picture of the role of the gastrointestinal tract in protein metabolism". To this end the subject was divided into six sections, but all thirty-four participants listened to each paper and this ensured a lively multi-disciplinary discussion which is faithfully reported in the book.

Section 1 deals with the digestion of proteins and has papers on factors affecting transfer rates along the gastrointestinal tract, on the heterogeneity of gastric proteinases and on the effect of soybean trypsin inhibitor on amino-acid availability.

Section 2 has five papers on the origin, magnitude and nutritional significance of endogenous secretion in non-ruminants. There was general agreement that such secretion is equivalent to a significant proportion of the normal dietary protein intake and therefore of great importance under conditions either of dietary inadequacy or of pathological failure to reabsorb the protein secreted into the gut. There was less unanimity on the suggested homeostatic function of endogenous nitrogen secretion in maintaining a uniform concentration and pattern of amino-acids for absorption.

Section 3 extends this discussion to ruminants in which the obligatory loss of nitrogen in faeces is shown to be a major determinant of nitrogen requirements. On the other hand, microbial activity in ruminants may actually enhance the value of dietary protein by amino-acid supplementation. It was suggested in the discussion that because the intestinal flora is quantitatively less important in healthy non-ruminants this does not exclude the flora assuming disproportionate importance under conditions of malnutrition and in the pathogenesis of the malabsorption syndrome.

Section 4 deals with protein digestion in relation to nutrition. It has a paper showing that the gastrointestinal hypertrophy of lactation is related to the increased intake of food. At the other end of the nutritional scale were three papers dealing with the biochemical and morphological changes in the gastrointestinal tract in experimental and clinical protein–calorie deficiency. A fifth paper reviews modern work on the diet–host relationships of the digestive flora, particularly in relationship to the use of antibiotics as growth stimulants.

Section 5 has four papers on the absorption of amino-acids, including fundamental studies on the mechanism of absorption and the practical possibility of using variations in portal amino-acid concentrations to investigate factors in feeds and rations affecting the digestion and absorption of dietary protein.

Section 6 deals with protein metabolism in subjects with enteropathies and other alimentary diseases, and has four papers on the progress being made in differentiating the metabolic lesions in diseases with common symptoms and end results.

Some of the papers represent the polished products of years of research; some are more in the nature of stop-press articles or progress reports. This, together with the discussion, makes for lively reading which can easily be extended because of the adequate treatment of references

and the efficient cross-indexing provided by the editor. The price is modest in relation to the central importance of the subject to anyone interested in the health or disease of animals or man. C. R. C. HEARD

GENES AND HISTONES

The Molecular Biology of Development

By James Bonner. Pp. vi+155. (Oxford: Clarendon Press; London: Oxford University Press, 1965.) 25*s*. net.

THE Molecular Biology of Development, written during the author's tenure of an Eastman visiting professorship at Oxford during 1963–64, is for the most part a résumé of several papers from his own laboratory. Its racy, colloquial style reads like, as it probably is, a transcript of the lectures he gave during this assignment. It certainly conveys his vivid enthusiasm for his thesis, which is that the histones are the natural gene inhibitors so that if the gene is covered with histones it is repressed, while if it is uncovered it is active. This is, of course, an attractive hypothesis and James Bonner makes the most of the limited evidence which can at present be adduced. A more cautious and critical survey of the evidence and possibilities would have been more useful.

Prof. Bonner states that his object is to apply the "framework of molecular biology" to the biological problems which remain to be solved. "It is my thesis", he says, "that we can now profitably go back and re-examine what it is that makes the differences between the different kinds of cells of a higher organism." The book may do good in directing the attention of research students to an enormous field of study which is just becoming accessible to investigation, but in which, although a few clues have been obtained, reliable signposts are still obscure. The fact is that the hypothesis by itself is not enough to explain the activity or inactivity of genes. It would be necessary in addition to explain what puts histones into their proper places and takes them off when required. The author has little to say on this, except for some mention of the possible intervention of hormones and other substances.

Although the enthusiasm is there, the facts are often presented in a slipshod and sometimes misleading fashion, and students would be well advised to supplement their reading by other sources. For example, the account given of the fractionations of histones in our laboratories can only be described as a travesty of the facts; three distinct methods are mixed up and as presented would certainly not work. Prof. Bonner would probably say that he did not aim at giving a precise account of these fractionation methods. But rather than a misleading account of details it would be better to say simply, as he indeed concludes, that "a variety of methods lead to the separation from calf thymus histone of four principal fractions".

Another example of loose reporting is the attribution to "Murray, 1964" of information on the *N*-terminal groups of histones. In fact all that K. Murray states in the paper quoted is that "Determinations of the N-terminal groups of the various histone fractions also indicate that the fractions are not homogeneous". Prof. Bonner's conclusion is "there is an interesting lack of heterogeneity amongst the histones with respect to the N-terminal groups". Conceivably both these statements hold some truth, depending on the point of view, but it is not reasonable to put forward a paper in which the only statement on the subject is that quoted first as a justification of the second. The fact that the information so far obtained is largely due to D. M. P. Phillips is not mentioned.

Readers who expect to learn much about development will be disappointed as the chapter on this subject (Chapter 12) is highly hypothetical and consists of a translation in 'computer language' of a sequence of processes involved in bud growth. The whole mechanism is described in a flight of fancy as "Digital organ generator Model A (DOGMA)". Evidently Prof. Bonner also has some doubts, since he concludes, "we do not yet know if the approach will be a fruitful one". J. A. V. BUTLER

PENICILLINS

The Penicillin Group of Drugs

By Prof. Gordon T. Stewart. Pp. xii+212. (Amsterdam, London and New York: Elsevier Publishing Company, 1965.) 55*s*.

THE discovery of penicillin is one of the few that deserve the hackneyed description 'epoch-making'. Fleming's original work in 1929 and the later development by Chain and Florey literally marked the beginning of a new era in the history of man. This antibiotic era has already profoundly changed the whole practice of medicine, but the special fascination of the penicillin group of drugs lies in their unique combination of medical and scientific interest. Prof. Stewart has tried, as he puts it, "pulling some of the strings together", and *The Penicillin Group of Drugs* is intended to illustrate "a continuing interaction of intellectual and practical endeavour".

The aim of the book then is clearly conceived, and the author has shown imagination and enthusiasm in defining it. But the achievement does not match the conception and the result is rather disappointing.

After a short preface setting out the purpose of the author in writing the book, the first three chapters deal with the history of the penicillins. Then follow chapters on the acid-stable penicillins, a chapter comparing the oral penicillins, and then one on methicillin. Three chapters are devoted to the mode of action of penicillins, and separate single chapters to toxicity (and pharmacology), resistance, allergy and epidemiology. The final chapter is on the cephalosporins.

The historical chapters are perhaps the best in the book. They are interestingly written, though sometimes in a semi-popular and rather dramatic style, and they give a good account of the various stages in the development of the different penicillins. But after these, in the chapters dealing with individual penicillins, the departure from chronological order has no advantages and something nearer the historical order of their discovery would have been in fact better. The isoxazole penicillins come more logically after methicillin than as part of a section on oral penicillins, since their penicillinase stability is a far more important reason for their use than their acid-stability, though this gives them one (sometimes doubtful) advantage over methicillin.

As regards the factual content of the book, there are many examples of facts incorrectly or ambiguously stated. On page 48, the statement that up to 50 per cent of strains of *E. coli* in some situations may form amidase is misleading and probably inaccurate. On p. 72 it is stated that methicillin has a high affinity for staphylococcal β-lactamase, but on page 145 it is stated to have a low affinity. On page 105 it is stated that the lactam-dihydrothiazine ring of 7-aminocephalosporanic acid is intrinsically more stable to most forms of β-lactamase than the lactam–thiazolidine (ring) of 6-aminopenicillanic acid. This is a loose and misleading statement: with some strains the reverse is true.

There are numerous mis-statements due to misprints, mis-spellings or verbal mistakes. For example, on page 149 the part played by *Trichophyton* species in protecting hedgehogs from infection by staphylococci (except by penicillinase-producing strains) is attributed to their ability to produce penicillinase. What is really meant is their ability to produce penicillin or a penicillin-like substance, as is correctly stated on page 161. On pages

92 and 107 'spheroblasts' should be 'spheroplasts'. On pages 38 and 39, in Formulae 3 and 4, for isoxazole penicillins R should be 'C_6H_4Cl', not 'Cl'. In Table 8 on page 100, the formulae of benzyl penicillin, methicillin, oxacillin and penicillin *N* are wrongly given. These and numerous other small misprints should be corrected in any future edition.

The title of the book alone is bound to appeal to many different types of reader, precisely because its subject-matter covers such a wide range of medical and scientific interests. In this sense the author has attempted to meet a real need, but because of its general and rather superficial nature the book steers a somewhat uncertain course between the extremes of an authoritative treatise on the one hand and a semi-popular essay on the other.

R. KNOX

CONTROL OF BACTERIAL DISEASES

The Battle Against Bacteria

A History of the Development of Antibacterial Drugs, for the General Reader. By P. E. Baldry. Pp. ix+102+8 plates. (London: Cambridge University Press, 1965.) 22*s*. 6*d*. net; 4.50 dollars; Paperback 10*s*. 6*d*. net.

THE belief that diseases were the results of supernatural invocations was prevalent until the first century B.C., when Varro postulated invisible organisms as the causative phenomena. Although knowledge was accumulated on the spread and control of diseases such as leprosy and plague, the identity of these organisms remained a mystery until the development of lens systems in the seventeenth century enabled Van Leeuwenhoek to describe bacteria. Later poor sanitation conditions were recognized as potential sources of cholera, typhoid and dysentery and the significance of 'carriers' also established. However, the battle was only fully engaged during the nineteenth century when methods of growing bacteria *in vitro* and evaluating some of their characteristic activities were devised. To-day the essential techniques pioneered by men such as Pasteur, Lister and Koch are taken for granted, but the whole of modern microbiology and therapeutics is based on their painstaking investigations and application to the task of allaying disease. Koch's now famous postulates, prompted earlier by his teacher Henle, were timely in dissuading bacteriologists from making unwarranted conclusions and established a strict protocol for the unequivocal identification of pathogens.

The assault on pathogenic bacteria came from two quarters: on the one hand, defensive measures in the form of vaccination, initiated by the work of Jenner on smallpox and enthusiastically developed by Pasteur and others; on the other hand, offensive measures using chemicals to kill bacteria *in vivo*. Here Ehrlich's concept of antimetabolism provided a basis for the chemotherapeutic attack, and the programme of antimetabolite research pursued by Ehrlich and Domagk led to the fulfilment of their aspirations with the discovery of sulphanilamide. Unfortunately, no mention is made in *The Battle Against Bacteria* of D. D. Wood's elucidation of the mode of action of this drug and the impact that it had on the later course of medical microbiology. The random approach to chemotherapeutics embodied in the search for antibiotics is treated in the final chapters where discussion is centred on a detailed examination of penicillin and streptomycin.

Dr. Baldry concludes by emphasizing the potentiality of many pathogenic bacteria to acquire drug resistance. The countermeasure of prescribing mixtures of drugs, as in the treatment of tuberculosis, was not, and indeed is not, always appreciated; as a result, gonorrhoea and streptococcal infections, for example, are not always susceptible to penicillin—the one-time panacea for all ills. Finally, our thoughts are focused on the increased longevity of man, due, at least in part, to drug therapy. In somewhat Malthusian terms, the author highlights the question of food supply and population control, and the consequences attending an increasing proportion of old people in the community. We are cautioned prudently that " . . . drugs have produced their own problems which, unless wisely handled, can lead to as much misery as the diseases themselves".

Dr. Baldry has produced a concise, accurate account of the development of therapeutic agents and, throughout, the book creates a sense of excitement in the reader, scientific fact being interspersed with profiles of the major figures, anecdotes and social comment. Aimed at the general reader, *The Battle Against Bacteria* will be read by non-specialist and specialist alike with much profit and enjoyment.

ALAN T. BULL

THE CELLULAR BASIS OF RADIATION LETHALITY

Mammalian Radiation Lethality

A Disturbance in Cellular Kinetics. By Victor P. Bond, Theodor M. Fliedner and John O. Archambeau. (American Institute of Biological Sciences and U.S. Atomic Energy Commission. Monograph Series on Radiation Biology.) Pp. xvi+340. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1965.) 76*s*.

TO understand the effects of radiation on higher organisms it is necessary to appreciate that the processes of cell division are disrupted by doses which are too small to produce measurable effects on the functions of fully differentiated cells. Thus tissues in which little or no cell division normally occurs may not appear to be affected by radiation, in contrast to those in which the population of functional cells requires continual renewal. In particular, animals will die if either the haemopoietic tissue or the epithelial lining of certain portions of the gastrointestinal tract became too depleted of stem cells and ultimately, therefore, of the functioning cells which arise therefrom.

Mammalian Radiation Lethality reviews most of what is known about the cellular kinetics of these two systems, and deals also with the central nervous system. One of the aims of the authors is to show how the perturbations introduced into the cellular kinetics by irradiation give rise to such radiation syndromes as are observed. Those portions of the book which deal with the kinetics of cell renewal are skilfully and adequately handled, and well documented, reflecting the many contributions in this field made by the authors, in particular Dr. V. P. Bond. Their touch is less sure, however, when they deal, in rather meagre fashion, with the fundamentals of cellular radiobiology, and it follows that the message of the book is not as forcibly delivered as it might have been. One chapter only, entitled "Basic Radiobiological Principles Derived from Tissue Culture Systems", is devoted to this major aspect of their main thesis, and an example of its sketchy nature is the omission of any references whatever to fractionation studies. Yet experiments carried out by tissue-culture techniques have demonstrated patterns which have been most impressively repeated in studies on the whole animal, and indeed, the authors have occasion to quote one such experiment, the very point of which was the evidence it provided that it was justifiable to interpret animal deaths in terms of dose effect curves pertaining to cells.

It is perhaps a part of the comparative inadequacy in the cellular radiobiology section that the documentation

is rather poor: for example, some data have been presented without references, although they were culled from only one or two papers, and there are some lapses in linking textual material with the references quoted at the ends of chapters.

The authors, in their preface, express the hope that "the material will prove useful not only to the advanced student but to the mammalian radiobiologist and the physician as well". This hope will be fulfilled if such readers concomitantly have at their disposal fuller and more authoritative sources of information on basic cellular radiobiology. On the other hand, this book will be invaluable to the cellular radiobiologist who is interested in the impact of his work on radiobiological investigation at a higher level of organization. When, after the Second World War, data on 'acute' radiation death started accumulating, it scarcely seemed possible that all the facts could ever be accommodated within one simple pattern. During the past decade it has become ever clearer that they can be, and much of the evidence, therefore, is here most usefully collected together.

TIKVAH ALPER

THE FUNGAL CELL

The Fungi

An Advanced Treatment. Edited by G. C. Ainsworth and Alfred S. Sussman. Vol. 1 : The Fungal Cell. Pp. xvi+748. (New York: Academic Press, Inc.: London: Academic Press, Inc. (London), Ltd., 1965.) 192*s*.

THE Fungal Cell forms the first volume of a three-volume treatise, of which the later two volumes will deal with fungi as whole organisms and with fungal populations. The purpose of the whole work is, to quote from the editors' preface, "to summarize what is known about fungi as fungi" and to serve as a reference book.

The fungal cell in its various aspects is dealt with in twenty-seven chapters by different authors. The first two chapters are introductory to the whole treatise, the first being a most readable historical introduction by G. C. Ainsworth, and the second, a summary outline for the non-mycologist of the structure and organization of different fungal groups, by C. J. Hickman. There follow five chapters on structural components of fungal cells (including cell walls, flagella, nuclei and ultrastructure of the cytoplasm), two on chemical constituents of fungi, five on cellular metabolism, fourteen on nutrition and growth, and a final chapter on gene action.

In general the coverage is very complete, but there are some gaps, especially in the section on cellular metabolism. D. J. D. Nicholas deals with the utilization of inorganic sources of nitrogen, but there is no chapter on amino-acid metabolism even though this subject offers scope for the kind of comparative treatment which would fit very well in a book such as this. More important, nothing is said about the regulation of cell metabolism by induction or repression of enzyme synthesis or by end-product inhibition of enzyme activity. The question of how far fungi share the regulatory mechanisms which have been demonstrated in so much detail in bacteria is an important one, about which a considerable amount can now be said. Perhaps the book was written a year or so too soon for a chapter on this subject.

Concerning the chapters which have been written, I have few serious complaints. Naturally enough some seem more interesting and readable than others, but all are written from expert knowledge and nearly all have excellent bibliographies. Here and there it seems that a greater integration of the different contributions would have been desirable. For example, C. F. Robinow and A. Bakerspigel deal with nuclear division in vegetative cells, while L. S. Olive covers meiosis and also touches on the post-meiotic divisions in asci. This somewhat artificial division of subject-matter is adhered to rather strictly, and one is left in some doubt as to whether there really is an important difference between mitosis in the ascus and mitosis in the vegetative mycelium, or whether the difference lies more in the different points of view of the respective authors. Each of these chapters is extremely interesting within its own terms of reference.

In one way this volume must have posed problems for the editors which will not arise with the later volumes. At the cellular level, especially in most of their metabolism, fungi are much the same as other organisms. One possible approach, and one which the reference by the editors to "fungi as fungi" might be understood to favour, is to take for granted, or to sketch in briefly, those aspects of cell structure and metabolism which are common to fungi and to other organisms, and to concentrate on those features of fungal cell biology which give the group its special characteristics. R. T. Moore, in his well-illustrated chapter on ultrastructure, takes this approach, dealing with cell-wall structure and septal pores, the behaviour of the nuclear membrane during mitosis, sporogenesis and haustoria. It might, in fact, have been better to have included some reference to, for example, fungal mitochondria, even if it was only to say that they were similar in structure to those of other organisms. One of the most interesting chapters dealing with the specifically fungal nature of fungi is that of N. F. Robertson on hyphal extension and branching, but the brevity of his account serves to emphasize how far we are from being able to account for even simple morphology in biochemical terms. The alternative point of view is represented by the chapters on glycolysis, by H. J. Blumenthal, on the tricarboxylic acid cycle, by D. J. Niederpruem, and on terminal electron transport by A. Lindenmeyer. Much of the space in these chapters is taken up with documenting the unsurprising proposition that fungi have, for the most part, the same enzymatic equipment as other organisms. This will no doubt be valuable for the fungal specialist, even though not very exciting for the general biologist. D. G. Catcheside's chapter on the rapidly moving subject of gene action has a rather different *raison d'être*. Here, although the general conclusions drawn are probably as applicable to other groups as to fungi, much of the best evidence comes from work with fungi, especially with *Neurospora crassa*.

Some diversity of treatment and approach is inevitable in a compendium of this kind, and it cannot be said to detract seriously from the value of the volume. This and the companion volumes seem likely to remain standard works of reference for many years to come, in spite of their extremely high price.

J. R. S. FINCHAM

TEA-GROWING

Tea

By Dr. T. Eden. Second edition. (Tropical Agriculture Series.) Pp. xvi+205+73 photographs. (London: Longmans, Green and Co., Ltd., 1965.) 45*s*. net.

THE first edition of *Tea* appeared in 1958 (see *Nature*, 182, 1577; 1958) with a second impression in 1960. This new edition does not differ fundamentally from the first, although a few sections have been altered or rewritten. The size of the book has increased by only four pages and the price from 35 to 45 shillings.

Tea is one of those tropical crops, like sugar cane, that are voracious consumers of nitrogenous manures, and these are all-important. The section on nitrogenous manuring has been rewritten and the results of recent experimental work incorporated. A feature of tea cultivation is the use of shade trees, usually leguminous. "Shade

and "Greenmanuring" is another chapter which has been redrafted and much additional or recent information provided. Among shade trees several species of *Albizzia* and *Erythrina* are discussed.

In the chapter on insect and other pests there are some alterations, notably in regard to mites. With tea the behaviour of mites is variable and a species economically important in one country or district is unimportant in another. Mite damage to tea is often seasonal and the usual sulphur sprays cannot be used because of taint to the tea, a non-tainting acaricide being necessary. The section on nematodes as pests of tea has also been rewritten, where experimental work with soil fumigants and the recent use of marigolds (*Tagetes*) for control is referred to.

Where tea is cultivated, in the wet tropics, the problem of weeds and weeding is usually especially severe. Weeding ranks second in labour costs on the average tea estate. The section on chemical weedkillers has been rewritten, which is not surprising having regard to the advances in this field in the past few years. Some of the modern herbicides that have shown promise in controlling weeds in tea plantations are referred to. Present indications are that weedkillers will secure adequate control but not eradication.

Another part of the book that has been altered or brought up to date is the final chapter ("Statistical Review") where acreage, production, consumption and distribution are dealt with. As the author points out, in a book of this kind great detail is neither possible nor desirable, and it must suffice to present the main data and point out the trends that seem significant, remembering that statistics can become out of date in a remarkably short time.

F. N. HOWES

BLAST DISEASE OF RICE

The Rice Blast Disease

(Proceedings of a Symposium at the International Rice Research Institute, July, 1963.) Pp. x+507. (Baltimore: Md.: The Johns Hopkins Press; London: Oxford University Press, 1965. Published for the International Rice Research Institute.) 15 dollars; 120*s*. net.

THE ideals behind the cliché that the object of agricultural research is to make two blades of grass grow where one grew before lose their force if those extra blades are diseased. Despite a good deal of research during the past thirty years the basic food of half the world, that is, rice, has been seriously curtailed by blast disease, which continues to spread geographically.

In 1949, the Food and Agriculture Organization set up a commission to place rice research on an international basis and a working party made steady progress towards this end, but it was not until July 1963 that an international symposium on blast disease was organized by the International Rice Research Institute (established in 1962) in the Philippines.

The Rice Blast Disease, which is the report of this symposium, is comprised of twenty-eight invitational papers contributed by participants from Asia and the United States, with proposals for intensifying international co-operation by the use of uniform blast nurseries, uniform procedures for resistance testing, and a joint study for differentiating races of the fungal pathogen. There is also an excellent bibliography of nearly nine hundred titles.

The range of research is comprehensive, covering the causal fungus, *Pyricularia oryzae*, the disease and its development, physiological races, the mechanism and genetics of resistance, breeding for resistance, and other methods of control. The morphology, taxonomy, host range, and life-cycle of *P. oryzae* are described, the author avoiding the pitfalls of early taxonomic literature. Nutritional requirements of the pathogen are dealt with, including the relationship of nitrogenous metabolites to the production of toxins and hence, probably, to greater plant susceptibility. Nutritional and cytological factors are further analysed in investigations of the physiology of the fungus and its variability in artificial culture.

Field studies have not been neglected and there are good accounts of the effects of environment and cultivar on disease incidence and the methods adopted for estimating crop losses and for forecasting disease outbreaks.

The problems of physiological races, the nature of genetics of resistance, the selection of test differentials, in fact, breeding for resistance at large, have a familiar ring, and it is admitted that information on these subjects is as yet meagre. There is need for a good deal more co-operation on an international basis in this sphere with the aim of much stricter standardization of techniques and materials, particularly genetically pure seed supplies.

Concluding papers on disease control recount the successful adoption on a field scale of phenylmercuric fungicides both in seed-beds and the field, and also the promising use of antibiotics. No mention, however, is made of mammalian toxicity of these fungicides except for a casual reference to eye injury by 'Blasticidin-*S*'.

It is a pity that such a report is marred by indifferent illustrations. It is not clear what useful purpose is served by many of the black-and-white text figures, and the coloured plates of leaf lesions are disappointing.

J. C. F. HOPKINS

DEVELOPMENT OF PLANTATIONS

Plantation Agriculture

By Dr. P. P. Courtenay. (Bell's Economic Geographies.) Pp. viii+208. (London: G. Bell and Sons, Ltd., 1965.) 25*s*. net.

THERE is a need for a general text-book on plantation agriculture, setting out the subject for the specialists in the natural and social sciences. Dr. Courtenay is a geographer. His background knowledge is therefore appropriate to the authorship of a book of this type; the stated aim is "to establish and analyse the distribution of this (plantation) distinctive type of crop production". His facts which, from the definition of the subject, are drawn from a wide variety of disciplines are accurate and well chosen; he emphasizes the important point, which has been obscured by political controversy, that many of the less-developed tropical countries owe much of their development to plantation enterprise.

However, as with many geographically biased books, the objective tends to be lost in the attempt to create a narrative. The treatment of the first part of *Plantation Agriculture*, concerned with the establishment and history of such agriculture, is better than the analytical treatment of the second part. Further, there tends to be a repetition of statements; this criticism applies particularly to the third section, in which Dr. Courtenay discusses in detail as case-studies the two plantation crops, rubber and tea. A more satisfactory arrangement would have been to conclude on discussion of the theme "the future of plantation agriculture", a subject of intense interest to students of tropical development.

A weakness is his approach to the crop environment, particularly rainfall variability in the so-called tropical 'regular-rainfall regions', to which the technologists, who are advancing plantation agriculture, are now paying much attention. For example, he states "the shoots of the tea plant grow with a distinct rhythm, unconnected with climate or other environmental conditions, which produces recognised flushing and dormant periods". Yet

he recognizes the 'over-wintering' of rubber and the enforced rest period in the northern areas of tea production.

The most satisfactory treatment is that of the social and economic aspects of plantation development. Siting of the first plantations was based on military security and ease of transport by water. Later sitings showed improved fit to agronomic criteria, but ease of communication remained important; plantations followed development of railways, not vice versa; and these social and economic factors, including those affecting supply of labour, still determine distribution to a large extent.

Dr. Courtenay rightly emphasizes the very large amounts of capital required to establish some types of plantation; the unit cost for a sugar factory, for example, is £2·25 million.

Diversification is considered to be a relatively recent policy, but in fact plantation owners were seeking diversification in the first half of the nineteenth century. To-day, plantation cropping is considered in terms of perennial crops; but this was not always so; formerly both tobacco and cotton were typical plantation crops. Dr. Courtenay's accounts of past economic difficulties help to put those of the present in their true perspective.

In considering the factors operating at the present time, Dr. Courtenay points out that price control, which has always been considered a prerequisite for the salvation of the smallholder, actually favours the plantation system. He also points out that in the total economy of a country, the cost of supporting services and social services must be added to small-holder production costs, whereas the plantation industry is self-supporting. In spite of these advantages he suggests that plantation agriculture may be on the decline.

As a whole, the book is of the right length for an introduction and is an appropriate short text-book for courses in tropical agriculture, agricultural geography and economics, and the specialists in the natural sciences.

W. R. STANTON

RAT GENETICS

Genetics of the Norway Rat

By Roy Robinson. (International Series of Monographs in Pure and Applied Biology. Division: Zoology, Vol. 24.) Pp. ix+804. (London and New York: Pergamon Press, Ltd., 1965.) 200*s*. net.

MOST people concerned with rodent genetics who, at some time or another, have had occasion to consult Grüneberg's excellent *Genetics of the Mouse* will probably have wished that a companion volume dealing with the rat also existed. This 800-page hand-book is a candidate for stopping that particular gap, and it would be a pleasure for me to be able to say that it succeeded in doing so in a manner worthy of its illustrious predecessor dealing with the companion species. Unfortunately, such is not the case, and this is for a variety of reasons.

Mr. Robinson has attempted an exhaustive treatment of the genetics of *Rattus norvegicus* in the form of an account of all the research bearing on such topics as colour variation, reproduction, endocrinology, resistance to disease and cytogenetics. There are seventeen such chapters in all, each of which is essentially self-contained. They can almost be regarded as separate monographs in themselves. This vast labour has been carried out in a most thorough but, it must be admitted, pedestrian fashion. The account of each investigation is usually given in the words of the original author, so that terminology frequently sounds old-fashioned. Moreover, the approach is essentially non-critical. Manifestly inadequate work is often given equal weight with more refined experimentation, even though minor criticisms are offered, albeit diffidently, from time to time.

But for anyone wishing for an introduction to one of the fields which Robinson has covered, the appropriate chapter will prove a veritable open sesame to the literature. Details of experimental procedures, often with diagrams of apparatus, are given, and the closest collation of different papers by the same authors attempted. Tables of results are often given in full, together with diagrams and graphs of the data. Coverage is essentially exhaustive. Thus the section on psychogenetics, which covers 167 pages, appears to lack only one reference which it might reasonably be expected to contain, and presents a wealth of new ones in every branch of this new and rapidly developing field. Indeed, since much of the significant work in psychogenetics has been done on the Norway rat, this chapter constitutes the most up-to-date review available of this modern specialization, and certainly the most comprehensive ever for the older work. Similar aspects of other chapters in this compendium could be singled out for praise, and Robinson's practice of repeating the details of experimentation relevant to the different topics he is dealing with, while it increases the length of the book, dispenses with the need for extensive cross-referencing and means that the chapters can be consulted separately with little fear of missing essential points.

Except in the case of a few diagrams where the word 'intercross' is shown as 'intercourse', an error which, while unfortunate, serves to reveal as much as to obscure, the book is relatively free from misprints. But it does suffer from numerous infelicities of style, which will grate on any reader with a sensitive ear for English, and from a determined confusion over the plural of the word 'datum'. Moreover, Robinson indulges a penchant for the rare word and the near neologism of which 'independency' and 'exercisation' are examples.

But these are relatively minor matters, which, while they detract from the overall impression of the book, must not be allowed to obscure its sterling worth, and can therefore be forgiven. What it is more difficult to forgive is the lack of a more adequate subject index than the present one, which occupies less than 1·3 per cent of the length of the book, and the price of £10 which the publishers have seen fit to attach to it.

For the manifest virtues of the compendium those concerned with any aspect of the genetics of this most important experimental organism will be grateful. The strictures I have felt it necessary to lay on the work as a whole are essentially blemishes, serious blemishes though they may be, but ones which can readily be cured in a later edition, the appearance of which will, no doubt, be eagerly anticipated by the many readers who will certainly find themselves indebted to Robinson before long.

P. L. BROADHURST

BRITISH GRASSHOPPERS AND CRICKETS

Grasshoppers, Crickets and Cockroaches of the British Isles

By Dr. David R. Ragge. (Wayside and Woodland Series.) Pp. xii+299+22 plates. (London and New York: Frederick Warne and Co., Ltd., 1965.) 42*s*. net.

THE group name Orthoptera, as Dr. Ragge admits in the introduction to *Grasshoppers, Crickets and Cockroaches of the British Isles*, applies to "a very diverse assemblage of insects", and its use, as well as a conservative classification, might be justified by a wish not to confuse a general reader. However, there are as yet very few British naturalists interested in these insects, and the new devotees who are certain to appear as a result of this book should have no difficulty in learning the system now adopted by specialists.

Introductory sections of the book deal clearly and competently with the methods of collecting, preserving and keeping the insects alive; the latter is particularly welcome because grasshoppers and crickets are undoubtedly more lively and interesting pets than the sluggish exotic stick insect, which is an old favourite. The chapters on the structure and habits are, inevitably, at the beginning of each group, because there is nothing in common in these respects between cockroaches and grasshoppers. Keys and descriptions of species are simple and clear but it is odd that the author measures the size of specimens as the distance from the front of head to the tip of flexed wings, or the end of abdomen, whichever is the greater; this practice differs from that adopted by all students of these insects and makes it almost impossible to compare the size of British specimens of a species with continental ones, although in some cases the differences suggest subspecific separation; no reason for this idiosyncrasy is offered. Special attention is paid to descriptions of adult coloration and its changes during life; E. J. Clark's system of colour notations is not used, but its exposition is useful, because of its potential value in studies of variation in natural populations; in the book, descriptive names of colour varieties are used—"green", "mottled", "black pale sides", etc. Macropterous forms, which should be called just that, appear under historical Latin names, without mentioning that these have no taxonomic standing. All species are given English names, some not very fortunate; thus while *Myrmeleotettix maculatus* is appropriately called Mottled Grasshopper, the name Lesser Mottled Grasshopper is invented for the unrelated *Stenobothrus stigmaticus*. The distribution of each species is shown on a Webster–Praeger map of counties and vice-counties, but the omission of maps for three localized species (*Decticus*, *Conocephalus concolor* and *Chorthippus vagans*) is regrettable, while the accidental distribution of domestic species is scarcely worth showing on maps.

Notes on habits of crickets, bush-crickets and grasshoppers are most useful; they include diagrams of their songs, and an excellent record of songs of the main species can be purchased with the book. One would wish that other features of behaviour and ecology were given more attention; for example, the eminent suitability of grasshoppers for population studies is not even mentioned.

The twenty-two colour plates, nearly all photographed from fresh specimens by the late H. D. Swain, are the best coloured illustrations of these insects ever published. The superb colour photograph of Great Green Grasshopper is, unfortunately, on the perishable dust-jacket, while it would do well as a frontispiece.

A brief, but pleasant, chapter describes excursions in some more interesting areas, and the book ends with a competent discussion of the distribution and history of the fauna against the background of geological, climatic and vegetational changes. The more recent effects of human activities—forest clearing, agriculture, grazing—are such that at present less than 20 per cent of the area of the British Isles offers suitable habitats for these insects. The rarer species are certainly approaching extinction, but nothing appears to be done for their protection, as is done for some butterflies.

Only few errors and omissions in this excellent book can be noted. It is not correct to say that the stridulatory pegs of female grasshopper are vestigial—they are merely less developed and in some females fully functional. Not all grasshoppers have four nymphal instars, since *Stethophyma grossum* has five. The bibliography omits an important paper by C. and P. Divers (1933) on the ecology and fauna of grasshoppers of South Haven Peninsula and my paper on the composition and origin of the British fauna (1930); interesting observations by K. G. Blair (1944) on *Conocephalus dorsalis* laying eggs in fly galls on reeds are not mentioned either in the text or in the bibliography.

One can confidently say that these long-neglected insects will now, thanks to this book, become as popular with Nature lovers as are birds and butterflies.

BORIS UVAROV

LIFE IS STRIFE

Animal Conflict and Adaptation

By Prof. J. L. Cloudsley-Thompson. Pp. xi+160+29 plates. (London: G. T. Foulis and Co., Ltd., 1965.) 42*s*. net.

PROF. CLOUDSLEY-THOMPSON uses the term 'animal conflict' in a very wide sense and applies it not only to conflict between animals but also to conflict between animals and their ever-varying environment. He regards it as the automatic consequence of change in the environment to which all living organisms must adapt themselves or perish. He points out, however, that the selection pressure of the environment does not directly produce adaptations but merely acts as a sieve that separates the more viable results of gene mutation or recombination from the less viable.

Animal Conflict and Adaptation is divided into four parts; the first gives an account of some of the physiological problems of adaptation such as osmotic regulation, respiration, and the change from aquatic to terrestrial life, and then considers some specific environments. As might be expected the author chooses life in deserts, both the hot ones of the great continents and the cold ones of the polar regions, to illustrate adaptations to particularly exacting environments. His personal experience of these regions and his researches, especially in the hot ones, give these chapters an enhanced value.

Part 2 deals with interspecific conflict, and concentrates attention on food chains and predators, parasites and disease, and how they act on population numbers. Part 3 turns on intraspecific conflict and discusses cannibalism, fighting, displacement activities, and conflict within the individual. Many of the carnivorous invertebrates are adapted to cannibalism, a density-dependent phenomenon especially in some insects that practise egg-cannibalism, but cannibalism is not commonly found among vertebrates, apart from the fishes and amphibians. Intraspecific fighting among the higher vertebrates is rarely fatal, and is generally ritualized so that dominance is established or territory maintained without serious damage to the species.

In the final part the author considers problems of conflict and adaptation in the human species—the menace to health by insects as the vectors of disease, and the human threat to wildlife. The latter is the disgraceful story of the destruction of the natural environment by man in ruthless exploitation, at first through ignorance, by now through greed; "few large animals exist on land to-day except in game parks and nature reserves". Is this destruction an inevitable part of man's evolution? Perhaps his evolution requires the elimination of most of the other land vertebrates to make room for his ever-increasing millions who want to live in an artificial, man-made environment and not in the natural one.

The final chapter brings the author to human population problems, and he suggests that many of them are the result of faulty adaptation and lack of restraint. When biologists consider these problems and think of the ever-surging flood of population growth, they foresee the future by extrapolating from what they know of animal populations. Their visions are not attractive—the human population is increasing at such a rate that within the comparatively near future overcrowding will be so intense that life as we now enjoy it will no longer be possible. It is probably too late now to regulate the size of the population by the

painless method of birth control; numbers will have to be reduced by killing off the excess either by famine, epidemic disease, or nuclear war—probably the latter, for conventional warfare is not effective. This history of civilization has always been discontinuous, and the present phase seems to be bent on its own destruction, after which some totally different phase may, or may not, succeed. It is certain that we cannot continue along our present path for more than a century or two. "Nature leads and science points the way—to the conservation of variety, to the rational exploitation of fisheries and game populations, to the control rather than the elimination of pests and parasites and to the stabilisation of human populations at an economic level. . . . We inhabit a small world and must learn to adapt ourselves to its limitations or perish . . . we are steadily destroying our world and may end up by destroying ourselves."

Prof. Cloudsley-Thompson has written a thoughtful and stimulating book; it is well illustrated, indexed, and provided with references to further reading, but there are too many misprints.

L. HARRISON MATTHEWS

THE BATS OF WEST AFRICA

The Bats of West Africa

By D. R. Rosevear. Pp. xvii+418+2 plates. (London: British Museum (Natural History), 1965.) 155*s*.

THE fascinating mammalian life of tropical West Africa has long been a subject of intense interest to zoologists. Students of the region will be deeply indebted to D. R. Rosevear for this superb monograph on its Chiroptera, the first comprehensive work of the kind yet attempted. *The Bats of West Africa* has been chiefly prepared with a view to the needs of young African scientists, but will prove to be of equal value to specialists in this field elsewhere.

The work covers the whole of tropical West Africa south of the eighteenth parallel of latitude north, to the coast, including Fernando Po Island; the eastern limit is the River Sanaga in Cameroon Republic, and thence north-east to Jebel Marra, following the watersheds dividing the West African drainage area from those draining to the Congo or the Nile.

A systematic check-list gives ready reference to the species occurring in the area and a general introduction to the Chiroptera provides fundamental information on their distribution, habits, reproduction, parasites, sensory perception and other important aspects of bat biology, as well as details of those aspects of structure of systematic importance. Methods of collection and preparation and measurement are also discussed and taxonomic practice and problems briefly treated. The systematic section which follows is well and clearly organized, with keys to the identification of genera and species, and useful synonymies. The information in the text is very full, covering the description, distribution, habits, biology and systematic problems of each species. The text is illustrated with very clear line drawings by Joanna Webb and the author, which greatly enhance the value of the work. A very full list of references, together with a list of journals with their abbreviations, is provided. A useful glossary of technical terms follows, and an illustrated account of taxidermy applied to bats will prove of value for those unfamiliar. A description of the zones of local vegetation is followed by a most valuable geographical gazetteer, supplemented by a folding-map at the back of the volume. *The Bats of West Africa* is a vital need for all serious students of African Chiroptera. It is comprehensive and eminently practical and will be a first source of information on its subject for many years to come.

D. L. HARRISON

FOSSIL MAN

Guide to Fossil Man

A Handbook of Human Palaeontology. By Michael H. Day. Pp. 289. (London: Cassell and Co., Ltd., 1965.) 42*s*. net.

IN the face of the present fashions in physical anthropology, it is a pleasure to review a book on fossil man, a subject seemingly dry as dust, and yet of fundamental importance to anyone interested in the study of man. Whatever we may learn of primate behaviour, it is human palaeontology which forms the basis on which knowledge of our origin and our nature can be built, and which alone can indicate the manner of the evolution of man. This *Guide to Fossil Man* is the first book of its kind ever to be produced in Britain, and we must be grateful to Dr. Day for undertaking such a task.

Apart from two short sections on the environment, culture, dating and anatomy of fossil man (22 pages), the book brings together information relating to forty key sites which have yielded "the bulk of significant hominid fossils". The sites are treated in turn, country by country, in the manner of a catalogue, and the information given for each fossil site is divided under a number of headings; synonyms; found by; geology; associated finds; dating; morphology; dimensions; affinities; original; casts; references. The information given is both accurate and quite extensive, and its value is much enhanced by numerous photographs.

However, this book represents the view of just one man on significant hominid fossils, and subjectivity is apparent both in the selection of the fossils and in their interpretation. It is not difficult to find fault with the selection of fossils which have been included. While on one hand we find an entry devoted to the very insignificant fragments from Ubeideya, of which both date and affinity are uncertain, there is at the same time no reference to any of the important skulls of Middle Pleistocene age from southern Europe, Russia and Persia. In fact the so-called Neandertal remains are very poorly represented, and while Dr. Day may feel that the distribution and character of these people are not of central significance to students of human evolution, they do represent the best recorded phase of this evolutionary process, and as such are wonderful material for students of human palaeontology. I would on no account feel justified in omitting a full consideration of this group in a course in human palaeontology. At the other end of the morphological sequence, it is remarkable that there is a six-page entry for the *Gigantopithecus* remains from China but no reference to the fragments classified as *Ramapithecus*, which have a claim to hominid status at least equal and probably much greater. At the same time, the late age of *Gigantopithecus* makes it clearly an interloper in any study of human evolution, while the early Mio-Pliocene age of *Ramapithecus*, and its remarkable morphology, make it more than merely a probable candidate for a stage in human phylogeny.

In contrast, Dr. Day gives very full treatment to the fossils from the early Pleistocene of Africa, and this part of the book is of real value as a record of what has been discovered in the Transvaal and in Tanzania. But here we must record that a very one-sided account is given of the significance of the Olduvai fossils, and the published opinions of such distinguished palaeontologists as Profs. W. le Gros Clark and J. T. Robinson, which represent an important body of opinion, are quoted neither in the text nor the references. Any book intended for students, let alone for professional reference, should quote widely in its treatment of controversial issues, since one of the most valuable exercises for any student is to make up his own mind on a controversial matter, and for this he must be well informed.

Though I believe these criticisms to be fair and justified there is nevertheless no real question of the value of this

well-produced book. Teachers will use it frequently, and so will students, and it should be on every library shelf. It is more than a pity, however, that every other time one turns to it for information, one draws a blank. The evidence for human evolution is still so slight that we cannot afford to overlook any part of it. The fossils which are missing are not unimportant and it is to be hoped that students will not treat them as such. But for what it contains, this guide fills a unique place as a most valuable text on human palaeontology. BERNARD CAMPBELL

SCIENCE AND SOCIETY

The Rise of the Technocrats

A Social History. By Prof. W. H. G. Armytage. (Studies in Social History.) Pp. vii+448. (London: Routledge and Kegan Paul; Toronto: University of Toronto Press, 1965.) 56*s*.; 9 dollars.

IN title, Prof. Armytage's book recalls Dr. Michael Young's *The Rise of the Meritocracy*, but there the resemblance ends. There is nothing futurist about Prof. Armytage's study of the place of the scientist in society and his influence on public affairs, though, regarded as a social history, the book disappoints. Covering roughly the past four centuries, its span is immense, and it is based on a range of reading that is vast and impressive. Prof. Armytage begins with the botanists and gardeners of the sixteenth century and traces the emergence of the scientific societies in the following two centuries, the beginnings of scientific and of technical education, the founding of the British Association for the Advancement of Science, to the establishment in our own times of the Department of Scientific and Industrial Research and the complex interrelations between Government, industry and the universities. In all this, he scarcely fails to note a significant factor or figure, and it is done, moreover, on an international scale which portrays the interactions of developments in one country or another. Mainly the treatment is pragmatic and practical, but sometimes he ventures into philosophy, as in his final chapter, "An Operational World".

The treatment varies considerably. There are imaginative and sensitive passages, but there are other much more pedestrian, which do not match the originality of the headings, and in which he seems sometimes so overwhelmed by detail that the wood is hidden by the trees. Sometimes, on the other hand, the passage of events is condensed to an extent that gives a picture of the situation which is not entirely accurate, and sometimes again his judgment seems to have been at fault in selecting trivialities, rather than significant factors or events, in order to make his point. Nevertheless, the overwhelming mass of detail which he has examined has not betrayed Prof. Armytage into jargon.

If, as a piece of social history, *The Rise of the Technocrats* disappoints, this is not because too large a canvas has been attempted or because the material is unbalanced. It is rather because Prof. Armytage nowhere defines what he understands by 'technocrat' and shows no clear understanding of the relations between science and technology to-day, particularly of their intellectual value. He describes events without pausing for any searching or satisfying examination of their real causes and leaves the impression at times that he is a little out of his depth. His quotations and references are copious and remarkably up to date, but he has at times a tendency to quote a secondary source when the primary one is even more accessible. Moreover, it is astonishing to find no mention of Tocqueville in an account of Anglo-American relations in the nineteenth century so full as Prof. Armytage gives us. Apart from this, the book is useful for its extensive references and bibliography alone, and the conscientious and painstaking reader should have little difficulty in correcting for himself any passages where either compression or imperfect judgment seems to have distorted the true picture. R. BRIGHTMAN

A HISTORY OF HYSTERIA

Hysteria

The History of a Disease. By Dr. Ilza Veith. Pp. xvi+301+14 plates. (Chicago and London: The University of Chicago Press, 1965.) 7.95 dollars; 59*s*. 6*d*.

DR. ILZA VEITH has essayed a difficult task in choosing hysteria for historical research *Hysteria: The History of a Disease* is timely, for at present hysteria is a controversial subject between neurologists and psychiatrists. The word itself no longer appears in the *Standard Nomenclature of Diseases*, and it was eliminated from the *Mental Disorders Diagnostic Manual* of the American Psychiatric Association in 1952, being replaced by the term 'conversion symptom'.

In spite of the long recognition of hysteria, over the centuries, to be a clinical entity, so eminent a psychiatrist as Dr. Eliot Slater in his Shorvon Lecture[1] holds there is no such disease. Sir Francis Walshe[2] in a recent paper, as a neurologist, defends the clinical unity of hysteria. He writes: "Apart from the mimesis of somatic disease hysteria may present, the dramatizations, the exaggerations and the pathological lying are also behavioural disorders, part of the total expression of the abnormal psychical state which is hysteria. A diversity of symptoms from case to case and, in any single case from time to time, no more destroy the unitary quality of the malady than the same diversities destroy that of disseminated sclerosis or of neurosyphilis". It is to be noted that Walshe also adds: "Nevertheless, Slater's nihilism in regard to hysteria is a challenge to neurologists once again to justify the concept of hysteria as a nosological entity in its own right". Dr. Veith also considers hysteria a disease. The extensive bibliography shows that she has read widely on the subject, and she sets forth much new and interesting information.

From early times in Ancient Egypt, hysteria (derived from ὑστέρα, the Greek word for uterus) was associated with uterine disorders, the symptoms being ascribed to wanderings of that organ. The remedies applied were designed "to cause the womb to go back to its place". The Hippocratic *corpus* described hysterical symptoms, such as the *globus hystericus*, carefully and also associated the disease with uterine displacements. Aretaeus considered the uterus a migratory organ, but noted that the malady also occurred in men. Soranus and Galen pointed out the fallacy of uterine migration.

In Chapter 3, Dr. Veith emphasizes that St. Augustine, Bishop of Hippo, regarded hysteria to be due to demoniac possession, induced by magic or witchcraft. For centuries in the Middle Ages many innocent persons were accused, tortured and executed for witchcraft. William Harvey investigated an accusation of this kind and was more enlightened than Sir Thomas Browne at a later date in that he secured a reprieve for four out of seven of the convicted witches. The sad story of the Salem witches is re-told, whose accusation was supported by so eminent a man as Cotton Mather (1663–1728). Even so late as 1749, a number of nuns were seized with mass hysteria and thought themselves bewitched by a young nun who was condemned and burnt alive in the market-place of Wurzburg.

Magic in the Far East is described and is followed by a chapter on hysteria in England. A striking example, which Dr. Veith does not mention, was the case of Queen Elizabeth I. She was subject to 'a spice of the Mother', as hysteria was termed, and, occasionally, had cataleptic seizures. Her malady was most apparent after the death

of Mary, Queen of Scots, when she held firmly to the belief that she had not authorized her cousin's execution, but had only signed the death-warrant as a precaution in case of Spanish invasion[3].

The medical beliefs about hysteria of later physicians of the past are recounted, including Edward Jorden, Sydenham, Cullen (who returned to the uterine theory), Pinel, Feuchtersleben, Griesingen, R. B. Carter, Jules Fairet, S. Weir Mitchell and Charcot, who studied the malady so brilliantly at the Salpêtrière Hospital in Paris and treated his patients by hypnotism.

Babinski, who was *chef de clinique* to Charcot, was able to show that hysteria was a nosological entity, although certain of its manifestations could be elicited by suggestion and eliminated by persuasion. Walshe[2] refers to this work, and also to the excellent summary of the psychopathology of hysteria by E. Mapother and A. Lewis[4]. The book concludes with an account of the work of Janet and J. Breur. Freud was Breur's pupil and the teaching of his chief led him to the evolution of psychoanalysis and the emergence of psychiatry as a specialized branch of medicine.

"Knowledge grows from more to more", and, as Dr. Veith mentions on p. 164, even Freud stated that the symptoms in some of his patients were not mentally determined or removable by analysis, but must be regarded as direct consequences of disturbed sexual chemical processes[5]. Dr. Veith suggests substitution of the term endocrinological for chemical.

We know to-day that certain manifestations of mental disease, such as general paralysis of the insane, and cerebral syphilis, are due to infection by the *Treponema pallida* and that forms of encephalitis have a virus causation. Again, powerful psychopathic drugs like those of the phenothiazine group produce effects very similar to those seen as sequelae of encephalitis lethargica. Walshe[2] observes that mass hysteria epidemics were attributed to witchcraft or demoniacal possession in past centuries, but "it is likely to-day that we should declare them to be due to some unknown and undiscoverable virus and call the condition encephalitis".

Research workers, including biochemists, may yet discover an organic basis for hysteria. In the meantime, Dr. Veith's admirable study will help reflexion and, possibly, suggest further methods of approach to the problem.

THALASSAEMIA

The Thalassaemia Syndromes

By D. J. Weatherall. Pp. viii+272. (Oxford: Blackwell Scientific Publications, Ltd., 1965.) 45*s*. net.

HAEMOGLOBINOPATHIES arise basically from an absence of normal adult haemoglobin. One mechanism is the replacement of the structural gene for normal adult haemoglobin (haemoglobin A) by one for that of an abnormal haemoglobin. Notably in the homozygote for the abnormal gene a red cell is produced which is too flat and has a shortened life span. Another type of haemoglobinopathy is called thalassaemia and is a consequence of an under-production of the normal adult haemoglobin, without a replacement by an abnormal variant.

The term thalassaemia is meant to denote an anaemia occurring in the Mediterranean, θαλαττα or θαλασσα being the Greek for Mediterranean Sea. The word has come to stay though it is an etymological monstrosity and conveys to a Greek the meaning of 'sea in blood'. Also, while thalassaemia was at first discovered in people of Mediterranean origin, it is now known that this 'Mediterranean' anaemia is widespread and that there are probably more Asiatics affected by this condition than there are Mediterranean people altogether.

The first step in clarifying the diagnosis of thalassaemia was the recognition that this under-production of adult haemoglobin could either be due to a failure in producing the α-chains of haemoglobin A or to one of providing the β-chains. As the α-chains of haemoglobin A ($\alpha_2\beta_2$) are shared with the other physiological haemoglobins F ($\alpha_2\gamma_2$) and A_2 ($\alpha_2\delta_2$), a completely different situation arises in α-thalassaemia from that of β-thalassaemia where only the normal adult haemoglobin is affected. There are numerous byways along which the normal haemoglobin A production can be diverted. Some of them have found their biochemical and genetical explanation as, for example, the formation of haemoglobin Lepore which consists of normal α-chains but has as its non-α-chain one which is composed of parts of the δ-chain and of the β-chain. It seems that thalassaemia may eventually be explained as a disturbance at one stage or another along a sequence of steps. This begins with the regulator gene giving permission to the operator gene to switch on the structural gene in the nucleus of the red cell precursor, and it ends with the assembly of amino-acids into polypeptide chains at the ribosome of the protoplasm under the guidance of the messenger RNA. There still remains a bewildering collection of thalassaemia syndromes which have not been tidied up and have not yet been explained on the basis of their genetics and their molecular biology. Nevertheless there is no field in human biology where insight into the synthesis of a macromolecule and its underlying genetical mechanism has been carried so far as in the investigation of the thalassaemias.

In *The Thalassaemia Syndromes* Dr. Weatherall has not made any concessions to simplification but he has succeeded in describing with great clarity the complexity of thalassaemia from every point of view, including those of genetics, clinical disease and therapy. His volume will be a standard work of help to geneticists and biochemists as well as to physicians and pathologists for many years to come.

H. LEHMANN

MEDICINE AND THE COMPUTER

Mathematics and Computer Science in Biology and Medicine

(Proceedings of Conference held by Medical Research Council in association with the Health Departments, Oxford, July 1964.) Pp. ix+317+12 plates. (London: H.M.S.O., 1965.) 60*s*. net.

THOSE who attended the Medical Research Council conference in July 1964 seem all to have agreed that it was a remarkable success in respect of the quality of papers presented and the opportunities for exchanges of ideas. Was insistence on publication of the *Proceedings* wise? The topics are not sufficiently closely related to provide a comprehensive summary of the present state of research in a field of science, and many papers are too short to stand alone either as broad reviews or as original contributions. This is not a criticism of the authors, whose papers may have been excellent for conference presentation and discussion, but of the belief that no conference is complete without full publication of proceedings.

The papers may be grouped as concerned with medical records, with classification problems, with epidemiology and therapeutics, and with physiological and cytological studies. Much of the first group consists of plans in outline or preliminary reports on record linkage. The range of ideas may have stimulated valuable discussion; in print

the impression is of eight authors making excellent proposals for different problems without the critical synthesis that could help in other situations. Newcombe's paper is outstanding for its account of large-scale record linkage in progress, though much of the content has been published before.

Sneath and Healy have illustrated very different multivariate statistical procedures for generating hypotheses relevant to classificatory problems, probably too briefly to be useful without reference to other papers that they summarize. Bailey's otherwise admirable statement of the logical problems of the logic of medical diagnosis is unfortunately tied to an assumption that circumstances are appropriate to assessment and use of prior probabilities. None of these papers makes much reference to computers except as a means of handling more variates than is otherwise practicable.

Among the papers concerned with epidemiology and drug therapy, Kendall displays his customary lucidity in explaining the mathematics of the spread of infection in a manner intelligible to non-mathematicians: Armitage raises important criticisms of sequential techniques in clinical trials.

About the time of the conference, several British universities were formulating plans for augmenting totally inadequate computing facilities. Projects regarded in the United States as straightforward applications of computers were totally outside the range of British installations, either directly for reasons of size and speed or because appropriate programming expertise could not flourish in the face of these inadequacies, and the gap was steadily widening. It is symptomatic of the attitude of British governments that only after eighteen months (and shortly after publication of this book) has preliminary approval been given to some of these plans. The type of loss we suffer is exemplified by the Lusted and Ruddle paper on analysis of chromosome karyograms, a description of a programming system that relates to a superb research technique and reads as dramatically as a 'thriller'. This paper puts others in its group in the shade, though Rosenblith gives a masterly survey of problems in the quantification of nervous activity. A series of papers on the mathematics of biological function includes interesting contributions on cell dynamics, tissue excitation, and brain topology (all speculative, especially this latter) and Whitteridge's excellent account of his work on the geometry of the visual cortex.

Undoubtedly this book will interest and benefit many readers, but publication of the more important papers in various journals might have made them more widely accessible at smaller cost. D. J. FINNEY

GENETICS AND PSYCHOLOGY

Methods and Goals in Human Behavior Genetics

Edited by Steven G. Vandenberg. Pp. xi+351. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1965.) 70*s*. 9*d*.

PSYCHOLOGICAL or behaviour genetics is the concern of an increasingly active group of psychologists and other scientists in the United States. *Methods and Goals in Human Behavior Genetics* is based on a symposium on the subject held in Louisville in 1963 and includes an edited version of the discussion which followed the papers read there. The sixteen contributors include six from University Departments of Psychology and representatives from biochemical genetics, agricultural biometrics, the science of animal behaviour, anthropology, child development and psychoanalysis.

There is a healthy diversity of opinion as to which aspects of human behaviour can most profitably be studied within a genetical frame of reference. Some would regard social criteria as the most important. On this view the contribution of genetic variation to academic achievement, or to the ability to patent scientific inventions, or to socially defined deviant behaviour, would be appropriate fields of investigation, even though simple genetic mechanisms will not be found. Others would prefer to start with traits such as hand clasping or tongue rolling in the hope that they may turn out to be inherited simply, but which may appear psychologically or socially trivial. In either case what is analysed is close to observed data. However, as psychologists, the majority of contributors prefer to analyse variables which they consider to have greater meaning psychologically, even though they may be more remote from direct observation. They may, for example, study scores on factors such as 'surgency', abstracted from responses to paper and pencil questionnaires. The form the genetic analysis typically takes is the calculation of 'heritability ratios' on data obtained from normal monozygotic and dizygotic twin schoolchildren.

It is when the contributors go beyond the calculation of h^2 from twin data that they are of greatest interest. Cattell, Vandenberg and others suggest theoretical extensions and refinements. There is clearly no lack of formulae. Yet others have been put forward in the United Kingdom. The difficulty is that findings are likely to vary widely, not only according to the population studied and the test used but also according to the method of analysis.

Among those who have attempted to replicate studies is Gottesman, who administered the same personality inventory to two different populations of twins. He is also one of the few to test parents as well as twins. After briefly reporting his findings, he goes on to speculate on natural selection and personality. Personality test score and fertility might be a fruitful area of research.

A perennial difficulty about the interpretation of twin data is the weight to be given to any greater similarity in the environments of identical than fraternal twins. R. T. Smith reports the opinions of 13 to 16-year-old twins on such points as whether they have different friends or different eating habits. It is interesting to have data of a more or less factual kind on points such as these, even though genetic factors may contribute to the environment to which a person is exposed. However, we are unable to assess the significance of such differences unless it is shown whether identical twins who differ in their taste in friends—or in vegetables—are in consequence less alike in health or personality.

A twin study which was not based on questionnaires is that of Freedman, using film, on the development of smiling and fear responses in infants. An interesting sidelight here is that the greater resemblance found in identical twins in these basic social reactions was unlikely to be accounted for by the mothers' handling. At that age (up to 8 months) most mothers of identicals thought their twins were fraternal.

It is perhaps typical of the psychologist's rather than the psychiatrist's approach that only one of the studies reported should be based on the relatives of psychiatric patients. This is the chapter by Mednick and Schulsinger, an American psychologist and Danish psychiatrist, who are investigating two hundred and seven children of schizophrenic mothers. The subjects were chosen because they constituted a high risk group. A recent Danish survey confirmed that about 12 per cent may be expected to develop the condition in time. The psychological, physiological and social data being collected will be used to test a particular psychological theory according to which schizophrenia is a learned disorder of thinking. The theory supposes the origins of schizophrenia to lie in the interaction of predisposing factors, possibly though not necessarily genetic, with 'unkind environments'. Already the children of schizophrenics have been found to differ from the matched control subjects in some of the expected directions. Although the hypothesis being

tested is not specifically related to genetics, the chapter fully deserves its place in the book since it illustrates one of the uses—the study of differences in identical twins is another—to which genetically derived material can be put. As most contributors realize, the calculation of numerical estimates of heritability is only one of the goals of human behaviour genetics.

One hopes the book will encourage a growing interest in genetics among psychologists and a reciprocal interest in psychology among geneticists. JAMES SHIELDS

HISTORY OF PSYCHOLOGY

A Source Book in the History of Psychology

Edited by Prof. Richard J. Herrnstein and Prof. Edwin G. Boring. Pp. xvii+636. (Cambridge, Mass.: Harvard University Press; London: Oxford University Press, 1965.) 100*s*. net.

THERE are very few books dealing with the history of psychology, and most of these have been written by Boring. The present *Source Book in the History of Psychology* is no exception, except that Herrnstein, also from Harvard University, has been made co-author. The book contains 116 excerpts from short to middling in length, and ranging in time from Epicurus (*c*. 300 B.C.) to the turn of the present century—and sometimes a little beyond. The arrangement is by topic; there are fifteen of these, covering such aspects as psychophysics, visual perception, cerebral localization, the reflex, association, and learning; within each topic the arrangement is in date order. The sections are preceded by a general statement in which the authors provide a setting for the reader, and individual excerpts are preceded or followed by quite brief notes which again are invariably helpful to the reader in directing his attention to points of interest, premonitions of later experiments or connexions with other authors.

It is very difficult to review a book of this kind; all that a reviewer could say after all would be whether he liked or disliked the particular choice made by the two authors. There can be few psychologists with sufficient temerity to argue the case with Prof. Boring, and in someone who does not have one-tenth of his historical knowledge or learning it may even seem presumptuous to say that on the whole the choice is excellent. However, taking courage in both hands, a few criticisms may perhaps be voiced, if only *sotto voce*.. In the first place, while we must welcome the inclusion of a section dealing with individual differences, these all deal with intelligence. Surely something could have been provided on personality ? Excerpts that come to mind are Kant's chapter on temperament in his *Anthropologie*, which was extremely influential and has found modern support in many factor analytic studies; Wundt's adumbration of the dimensional approach in his *Physiologische Psychologie*, and Binet's very important description of the personality differences between his two daughters.

These omissions are perhaps symptomatic of the tendency of the authors to restrict the term 'psychology' somewhat unduly; we have Fechner on Fechner's Law (predictably enough !), but why not Fechner on experimental aesthetics ? His discussion of aesthetics (*Von Oben Und Unten*) is a classic which should not be omitted in a book like this. In a similar way we are given Hartley on association but we are not given his extremely interesting and forward-looking discussion of the application of associationist principles to criminology and other important human activities. It might be objected that where something new comes in, something else has to go out, but in answer one might perhaps feel that some of the selections are more relevant to physiology than psychology.

It will be seen that even these criticisms are more a reflexion of my own preferences than firm indications of the dereliction of the authors; they certainly do not for a minute diminish the importance of this book, which may serve to lead many psychologists into an appreciation of historical writings which at the moment is so sadly lacking. We already owe so much to Boring that it is a pleasure to welcome this latest Harvard effort, and to wish it the success it so richly deserves. H. J. EYSENCK

INVESTIGATION OF SOCIAL STATUS

Roles

An Introduction to the Study of Social Relations. By Michael Banton. Pp. ix+224. (London: Tavistock Publications, Ltd., 1965.) 21*s*. net.

WRITERS who concern themselves with social class are legion; few approach their chosen causes in any spirit of scientific enquiry. Yet better regard for this complex field of social relations is essential for human and social development and, in *Roles*, Prof. Michael Banton has not only made a timely and conspicuous contribution to existing knowledge but has also provided a great stimulus to further investigation.

Using material obtained from studies of primitive, peasant and industrial societies, he analyses different kinds of social structure in terms of roles. Banton's approach is different from that of other sociologists, however, in that he is less concerned with the behaviour of people who occupy various roles (their 'context') than in the implications of the inter-relations between roles. Various definitions of concepts like status, class, prestige and esteem are examined and from these Banton builds up a theory of roles involving a rough, threefold classification into basic, general and independent. His basic roles are concerned with distinctions of sex and age, race and rank, and "are those which predetermine most of the positions open to an individual and which have implications for the way the parties behave towards one another in a correspondingly large proportion of social situations". General roles are usually allocated to individuals in accordance with their qualifications and are frequently associated with activities of a religious or political character. Independent roles are associated with individual merit, examples being most leisure roles and many occupational roles in industrial societies. From these definitions, Banton expands to examine, in greater depth, the connexion between economic development and role strains; role signs; role-changing; roles and the self; the compatibility of roles; the prestige of roles; and the relation of social density to order and progress.

Such a thoughtful and original work could scarcely be free from error or issues where different observers would place different emphasis or interpretations. Banton, for example, has misjudged the pace at which men are taking over home roles of women (for example, matrons in hospitals) and the reason that doctors prefer not to treat members of their own families. He labours the psychological ramifications of incest and neglects genetic drawbacks. He also needs to delineate more clearly the difference between job status and personal prestige and their significance for all kinds of workers in industrial communities. In a book which is based on wide survey and scholarship in many disciplines, however, Banton expostulates so persuasively that most readers should welcome *Roles* as a worthy descendant of T. H. Marshall's study of social class in 1934. The transparent simplicity of the writing adds value to the text and altogether makes this one of the most outstanding contributions to sociology during the past three decades. It could profitably be used in the education of all who are concerned with people, whether primitive or from industrial societies. This

volume, and others which should stem from it, should lead in constructive manner to greater understanding and skill in social control. T. H. HAWKINS

THE BEST USE OF MATHEMATICAL INNOVATION

The Best Use of Economic Resources

By L. V. Kantorovich. English edition edited by G. Morton. Translated from the Russian by P. F. Knightsfield. Pp. xxxiii+349. (London and New York: Pergamon Press, Ltd., 1965.) 100*s*. net.

THE Best Use of Economic Resources is an important book for the historian of economic thought, a valuable one for the economist anxious to improve his technical capacity, and a fascinating one for those interested in the development of the economy of the U.S.S.R.

Linear programming is a mathematical technique with many important applications in economics. Kantorovich was probably the first to use it (in 1938) and to publish on it (from Leningrad University in 1939). The first Russian edition of this book was published by the Academy of Sciences in 1959. This edition in English now enables a comparison to be made between Kantorovich's approach and the techniques independently developed since, mainly in the United States.

The book confirms the view, or prejudice, that to find close similarities in independent discoveries of mathematical techniques is less surprising than, for example, in theoretical model building. Even where Kantorovich considers that his methods differ significantly, for example, from Dantzig's simplex-method, the similarities seem greater than he imagines. The references Kantorovich cites to the American work are very early ones and perhaps he was unaware of the extent to which their refinements paralleled his own.

Kantorovich's exposition of his techniques is admirably lucid, well stocked with helpful numerical examples and requires only a minimum of elementary algebra from the reader. One problem dealt with is how best to allocate a desired output of two (later three) products between a number of factories. Another is how to determine the best combination of factors of production with which to produce a given commodity. Kantorovich's concept of 'objectively determined valuations' plays a key part in his techniques for taking optimum decisions. These 'shadow prices' are used to determine the least-cost combination of factors of production and the allocation of output between enterprises. These methods of picking out least-cost solutions from a wide range of complicated possibilities are surely among the most important contributions made by mathematicians to laying foundations for human happiness.

Where Kantorovich touches on the relationship between the process of pricing and allocating factors of production on the one hand and the pricing of commodities on the other, his exposition is not so clear. When he wrote this book Kantorovich was trying to convert Russian planners to the use of more cost-conscious criteria when taking decisions about production. This ran into ideological resistance, because of the view that any identification of costs with scarcity was a challenge to Marx's labour theory of value. Several critical qualifications of this sort are made by the late V. S. Nemchinov in an editorial preface. To argue that scarcity should determine commodity prices was open to additional criticisms, of subjectivity and of suggesting that market forces should supplement or supplant decisions on priorities taken by the planners. Planning methods in the U.S.S.R. have made progress in the seven years since this book was first published, with enterprises enjoying greater autonomy to enable them to respond to the market forces which now exert considerably greater influence on the pattern of production. Much that was either obscure to Kantorovich (or obscured by him) would probably now be treated with greater clarity and directness.

Even now, of course, Russian economists would not claim that this partial equilibrium analysis could be integrated into a general equilibrium system. Their situation in this respect is little different in practice from that of Western economists, who recognize that because of the structure of industry in advanced capitalist economies the integration of their partial and general equilibrium analyses can only take place in theory. But it is useful to have a general equilibrium theory, if only to provide a contrast to the way the economy works in practice. Kantorovich's book is not an attempt at a general equilibrium theory of a planned socialist economy, and so far as I am aware, Russian economists have not yet produced such a general idealized model of their planning system. The changes in economic thinking and practice in the U.S.S.R. bring nearer the time when somebody could. K. J. W. ALEXANDER

RULE-OF-THUMB STATISTICS

Statistical Methods

By Prof. Stefan Szulc. Translated from the Polish by J. Stadler. Translation edited by H. Infeld and C. D. I. Forrester. Pp. viii+666. (London and New York: Pergamon Press, Ltd.; Warszawa: Państwowe Wydawnictwo Ekonomiczne, 1965.) 105*s*. net.

THE title *Statistical Methods* is a slight misnomer. The book is almost exclusively concerned with the collection and presentation of statistical data, mostly of a demographic or economic nature. It discusses, though not very thoroughly, data processing, but punched cards and the machines associated with them are described as if they were the most modern thing in a statistician's equipment; electronic computers are not mentioned at all. This probably explains why the calculation of multiple correlation coefficients is regarded as "very arduous" (p. 489).

The concept of probability is discussed only in a chapter of sixteen pages towards the end of the book. An idea of the vagueness of the treatment can be derived from the following 'definition', set out in italics: "*The probability of an event is the ratio of the number of cases favouring the event to the number of all possible cases (those favouring the event and those not) assuming that all these cases are equally possible*" (p. 505). The late author admits, it is true, that "this definition is not correct from the formal point of view", but no correct definition is given later. Thereafter one is not surprised to find no mention of the concept of a probabilistic model, without which no statistical interpretation of raw data is possible. This applies, in particular, to the problem of smoothing statistical data, eliminating random disturbances, and discovering trends; but then this question is treated in advance of the little chapter on probability. The vagueness of the approach to theoretical considerations is further illustrated by the following sentence: "The property of the averages is that by substituting an appropriate average for the particular values of the variable we obtain for the whole population the same result as we would get by taking into account individual values corresponding to particular observations" (p. 170).

This quotation gives also an idea of the quality of the translation. One cannot expect high standards when publishers use translators whose work has to be 'edited' by somebody else. In any event, the editors failed, for example, to provide references to existing English translations of books quoted in Polish translations; however,

they seem to have been careful about the syntax of the first thirty pages.

It is a pity that the Polish statistical literature, rich as it is in excellent publications, should now be represented by a book which was obsolescent when the original appeared twelve years ago. However, a practical statistician can still find in it a great deal of shrewd advice on gathering and presenting statistical data, and even curious examples of deliberately misleading graphs. The wealth of examples is certainly instructive in many ways, and notes on the early history of statistics, going as far back as Biblical times, are very interesting. A few statistical tables are always welcome. The book is well produced.

S. K. ZAREMBA

ESSAYS OF TEILHARD DE CHARDIN

The Appearance of Man

By Pierre Teilhard de Chardin. Translated by J. M. Cohen. Pp. 286. (London: William Collins, Sons and Co., Ltd., 1965.) 25*s*. net.

THE Jesuit Teilhard de Chardin was a really great man. He was born in Central France, the son of what in England would have been called a 'gentleman farmer'. In his maturity, he was in the front rank as a palaeontologist, he was a first-rate geologist, a philosopher of note, and a profound Christian. Attention has to be paid to the opinions of such an individual. His books are widely read and have been translated into English. Indeed, at the moment, quite a cult of Teilhard de Chardin has grown up.

In spite of the foregoing facts, what, one is driven to ask, is the object of publishing or republishing old essays, some of which date back to 1913 and 1921? The subjects which Teilhard professed are rapidly expanding and changing as new information comes to hand. In 1921 Boule's book was the last word on the subject of fossil man and Teilhard's opinion of it was at that time well worth knowing; but nowadays much has changed—including, naturally, Teilhard's own attitude to many problems. Indeed, the later essays in *The Appearance of Man* show this to have been the case. Of course, where he is writing of factual finds, of excavations in which he took part, the articles are dateless and invaluable. Such is the case for the two essays on Pekin Man. Again the illustrations in the essay entitled "The Question of Fossil Man" are particularly well chosen and useful: if one were asked to produce an illustration of Baron Blanc's Mousterian find of the Monte Circeo skull one would be hard put to it to recall where this was published, but it appears in this essay. Naturally the later articles are of much more contemporary interest, especially those written after de Chardin's visit to South Africa towards the end of his life.

As an old friend of Teilhard I am glad to possess this book because, as well as being pregnant with new ideas, it also shows the evolution of the author's own thought, and perhaps it is in some sense as a historical document that it has been published. But anyone reading it for instructional purposes should note carefully the date when any particular essay was written. There is a preface by Desmond Collins which indeed briefly attempts to bring the reader up to date, and this, of course, is very helpful. Nevertheless this volume should not be classed with such works as *The Phenomenon of Man*, *Le Milieu Divin*, or *The Future of Man*. It is obviously not fair to compare a collection of purely scientific essays with those great works of philosophic thought, but I can only feel that Teilhard himself would have gently but gravely protested against the republication of some of his writings which he would have been the first to describe as *vieux jeux*.

M. C. BURKITT

JOHN HUNTER'S MUSEUM

History of the Trustees of the Hunterian Collection

By Sir Victor Negus. Pp. viii+132+7 plates. (Edinburgh and London: E. and S. Livingstone, Ltd., 1966.) 30*s*. net.

AN inestimable debt of gratitude is owed to two medical men who have enriched knowledge by their collections, now held by trustees for the nation. One was the physician, Sir Hans Sloane, founder of the British Museum, the other the surgeon, John Hunter, whose memory is perpetuated by the Hunterian Collection.

Hunter in his Will desired that his museum should be kept intact and if no other purchaser appeared that it should be offered to the Government. He died in 1793. Soon afterwards England was at war with France. Dr. Matthew Baillie, Hunter's nephew, and Everard Home, his brother-in-law, approached the Prime Minister, William Pitt, who said: "What! Buy bottles? We have not enough money to buy gunpowder".

Nevertheless, in 1796, a committee was appointed to report; they advised purchase of the collection. Three years elapsed, and then in 1799 the Company of Surgeons, reconstituted by Royal Charter, received a parliamentary grant of £15,000 for the purchase and undertook to maintain the museum. Further grants were given later. In 1800 the Company became the Royal College of Surgeons of London. Trustees, pre-eminent in science and public life, were appointed and William Clift, Hunter's devoted assistant, was appointed curator. The Government also made certain terms and conditions of the Trust including a course of lectures on comparative anatomy. By 1818 the museum found a permanent home in the Royal College of Surgeons in Lincoln's Inn Fields.

The original collection comprised some 13,682 specimens. The physiological section was in two divisions; the first illustrated the structure and parts of a plant, animal or man, and the second concerned the reproduction of the living individual, thereby continuing its species. Another division included pathological specimens and illustrated the effects of disease or injury on normal structures. Other, smaller sections contained specimens of human and comparative osteology, geology, monsters and malformations, undissected animals, vertebrates and invertebrates and stuffed animals and birds.

History of the Trustees of the Hunterian Collection recounts the later history of the Trustees and the museum. Sir Victor Negus gives concise notes of the eminent scientists who have cared for and increased the value of the collection; for example, Sir Richard Owen, Sir William Flower, Sir Arthur Keith and Dr. Wood Jones, the first Sir William Collins professor of anatomy and conservator of the Anatomy Museum.

During the First World War, storage in a sub-basement sufficed for protection of the collection. In the Second World War, although extra precautions including strengthening of the sub-basement were adopted in 1940, they proved inadequate in view of the increasingly destructive power of high explosives. On the night of May 10–11, 1941, a high-explosive bomb destroyed two-fifths of the original Hunterian specimens and three-fifths of the 60,000 specimens including the valuable collection made in the First World War. By careful salvage, about 26,000 out of 60,827 specimens were saved. The president of the College, Sir Hugh Lett, and the acting chairman of the Museum Committee, Sir Gordon Gordon-Taylor, procured accommodation for the salvaged collection at various institutions and private centres in the country.

At the conclusion of the War the collection was gradually brought back to Lincoln's Inn Fields. The specimens, with further additions, have now been arranged by Miss Jessie Dobson, the anatomy curator, in the rebuilt portion of the College. Generous contributions have been made by the Wolfson Trustees, by the MacRae Webb-Johnson Fund and by Fellows of the College.

Sir Victor Negus has dedicated his excellent *History* of the Hunterian Trustees to the memory of John Hunter. It shows how the Trustees have well maintained the purpose of the collection to teach scientific surgery to undergraduate and postgraduate students. Hunter brought an observant scientific mind into the study and practice of surgery and in the Hunterian Museum this abides to-day.

ANTARCTICA

Antarctica

Edited by Trevor Hatherton. Pp. xvi+511. (London: Methuen and Co., Ltd., 1965.) 90*s*. net.

EVEN a cursory acquaintance with conditions in Antarctica is sufficient to enable one to understand why it has stimulated the interests of explorers and, more recently, of earth scientists even if, to date, its economic importance is represented only by a declining whaling industry. For those who approach the Antarctic via the South Atlantic, the first view of a typical landscape is South Georgia, a mountainous island with extensive glaciers and a fringe of vegetation consisting of lichens and coarse grasses. The fact that it is, nevertheless, at the same latitude as Sheffield emphasizes the contrast between the southern and northern hemispheres: that civilized life can exist in northern Europe at latitudes which involve considerable survival problems in the southern hemisphere.

Less than one-tenth of 1 per cent of the fourteen million square kilometres of continental Antarctica is free from the ice which averages 2 km in depth over the continent as a whole. The removal of this ice would raise the level of the oceans by 60 m, while the land surface of the continent would rise by some 600 m through isostatic compensation. Nevertheless, Antarctica is an arid region with a precipitation of only 12–15 cm equiv. of water per year. This, however, is sufficient to account for the vast tabular icebergs which break away from the perimeter of the continental ice shelf. Antarctica also has its oases, like Lake Vanda with a permanent ice cover 4 m thick and yet with a temperature of 26° C at its bottom. Is there net accumulation of ice over the continent? What is the explanation for the thermal balance in the 'oases'? Almost every statistic about Antarctica raises questions to which answers are still being sought.

Antarctic research is carried on by some twelve nations and, although the primary scientific reason is the extension of man's knowledge of his global environment, there are respects in which it may contribute to his more immediate well-being. The extension of meteorological observations is relevant to weather prediction throughout a vast area of the hemisphere while ionospheric data are important in connexion with radio communications, which are especially difficult in polar regions (due to auroral and associated phenomena).

The heroic era of Antarctic exploration which commenced with Captain James Cook's circumnavigation in 1772–75 finally gave way to intensive scientific investigation, with the final great journey in 1957–58 of Fuchs and Hilary coinciding with the International Geophysical Year which brought into being a vast international scientific programme. This has largely been maintained and, indeed, has been extended during the International Years of the Quiet Sun of 1964–65. Intensive land-based scientific work on any scale is very recent indeed and may be said to date from the creation, in 1943, of the Falkland Islands Dependencies Survey with the establishment of a number of stations in the Antarctic Peninsula (formerly Graham Land) and the initiation of a detailed survey, regular weather observations, etc.

The present volume, entitled *Antarctica*, is edited by Trevor Hatherton on behalf of the New Zealand Antarctic Society. Hatherton was New Zealand's chief scientist for the Antarctic during the International Geophysical Year and his twenty-two contributors are drawn from the United States, New Zealand and the United Kingdom. The subject-matter is divided into four main parts: the nations in Antarctica; the southern ocean; the antarctic continent; the south polar atmosphere. Each author is a specialist in his field and to some extent this is a book for specialists. On the other hand, it is characteristic of Antarctic research that few who embark on it can avoid developing wider interests outside their own speciality. The present volume will therefore help the individual to acquaint himself with what his colleagues in other scientific disciplines are doing and enable him to set his own work in a wider context.

With so many contributions it is unfortunately possible only to make a selective review.

The first chapter offers a historical survey of national interests and activity in Antarctica from its discovery until the Antarctic Treaty. Some may regard this latter as the most important outcome of the International Geophysical Year, representing a political reconciliation of competing territorial claims in which the U.S.S.R. and the United States joined in taking a leading part. The Treaty is quoted in full in an appendix and it is, perhaps, worth recalling here the following extracts:

". . . Recognising that it is in the interest of all mankind that Antarctica shall continue forever to be used exclusively for peaceful purposes and shall not become the scene or object of international discord; . . . There shall be prohibited, *inter alia*, any measures of a military nature. . . Freedom of scientific investigation in Antarctica and cooperation toward that end, as applied during the International Geophysical Year, shall continue, . . .".

Chapters 2 and 3 deal with "Techniques of Living, Transport and Communication" and with "The Mapping of Antarctica" respectively. While the advent of the aeroplane together with the tellurometer has revolutionized mapping, it is nevertheless true that dogs are in many cases still the safest and often the only suitable means of transport. Living has its own problems, especially when men must live underground like rabbits while maintaining apparatus for scientific observations above the surface.

Chapters 4–7 deal with oceanic Antarctica, the movements of both water and ice pack, the ocean floor, the fauna and the abundant higher species of birds and mammals. The section on the continent, Chapters 8–14, discusses the physical characteristics and dynamics of production and wastage of the Antarctic ice, the distribution of land below the ice and its geology, as well as the flora and fauna.

The final section (Chapters 15–18) is concerned with the south polar atmosphere, its meteorology, the upper atmosphere and ionosphere, and the polar geomagnetic field and its fluctuations. The Aurora Australis, like its associated Boreal phenomenon, occurs most frequently in a zone within the polar region and is allocated a special chapter (Chapter 16). The aurora is closely associated with geomagnetic disturbance produced by electric currents flowing in the auroral regions, and it is interesting to note that it was this connexion that led C. F. Gauss to speculate so long ago as 1839 on the existence of an electrically conducting upper atmosphere. We now know that a primary mechanism in auroral production is the precipitation, down magnetic lines of force, of energetic electrons and protons. Thus one important aspect of Antarctic auroral research is concerned with studies conducted simultaneously in both hemispheres from stations which are connected by the same geomagnetic field line. Gauss spoke of the "enigmatic phenomena of the Polar Aurora"; after a lapse of more than a century it still has its mysteries to be resolved.

Antarctica is, technically and scientifically, a volume of considerable merit and is provided with an up-to-date map (scale 1 : 16,000,000) on which are indicated the locations of the various scientific bases. T. R. KAISER

SHORT REVIEWS

Satellites of the Solar System

By W. Sandner. Pp. 151. (London: Faber and Faber, Ltd., 1965.) 36*s*.

THIS is an interesting book in that it confines its attention almost entirely to the natural satellites of the planetary system; reference to the primaries is made only when necessary to clarify some point of the description. After a brief introduction to the history of observational work and the laws of Kepler and Newton, the author deals first with the satellites of the planets beyond Mars and returns to the inner worlds near the end of the book.

The work suffers little in the translation, and will appeal to the interested layman as well as to the amateur astronomer; indeed, some of the references to early observational work are rarely seen in more advanced works, yet they can, when separable from defects of optics and technique, be quite useful.

The few faults in mathematical notation will not distract the casual reader, and those who do detect them will also realize what is actually intended. This book is a useful contribution to the literature for those at the beginning of an interest in our closer neighbours in space.

L. WILSON

Elements of Geochemistry

By Prof. Yasuo Miyake. Pp. 475. (Tokyo: Maruzen Company, Ltd., 1965.) 12 dollars.

THIS text-book is said to be a modernized revision and translation of a work in Japanese first published in 1954. Although it bears a 1965 date-line, reference to investigations published later than 1958 is restricted to the mention of a few papers from Japan; and as a consequence of this lack of observations drawn from the recent vigorous growth of geochemical science elsewhere, some of the information which the book presents is obsolete. For example, a section on 'the oldest rocks' is based on a paper of 1952, giving maximum ages of no more than 2,200–2,400 m.y. instead of around 3,500 m.y. Not one of the great range of contributions published since 1956 in the Russian periodical *Geokhimiya* is referred to, although this journal is available in English translation. In his preface, the author rightly observes that he has paid more attention to the boundary problems between astronomy, geophysics and geochemistry than to a general review of geochemical science; and he claims that more space is devoted to cosmochemistry and to the geochemistry of the atmosphere and hydrosphere than in other texts of this kind. Since, however, his treatment of the chemistry of the Earth's crust compares somewhat unfavourably with that of geologically oriented works available at a lower price, it is difficult to recommend the book as a teaching text, particularly as it has received insufficient editing to ensure uniform clarity of presentation and eradication of the very many misprints.

C. F. DAVIDSON

The Collected Papers of Lord Rutherford of Nelson, O.M., F.R.S.

Vol. 3: Cambridge. Published under the scientific direction of Sir James Chadwick, F.R.S. Pp. 428+10 plates. (London: George Allen and Unwin, Ltd., 1965.) 90*s*. net.

THE third volume of *The Collected Papers of Lord Rutherford of Nelson* contains his work while Cavendish professor at Cambridge from 1919 to 1937. This was his mature period when, having laid the foundations of nuclear physics, he directed an already famous laboratory with very great distinction. Naturally the earlier papers in the volume are the most important; presumably later in the period he devoted more of his time to the general welfare of the laboratory and to advising and encouraging the many able physicists who visited the Mecca of nuclear physics.

The most important papers deal with the very occasional production of long-range protons when light nuclei are bombarded by α-particles. Rutherford correctly interpreted these observations as evidence for the absorption of the α-particle by a nucleus with the subsequent emission of the fast proton. For the first time the disintegration of light nuclei had been observed.

Rutherford's Guthrie Lecture of 1927 on "Atomic Nuclei and their Transformation" is a very clear summary of all the work of himself and his colleagues on the interactions of α-particles, including the rare disintegrations. He speculated freely about nuclear structure and nuclear forces and produced some fascinating nuclear models.

Together with some young colleagues, Rutherford performed several beautiful experiments on the very sure long-range α-particles emitted from radium *C* and correctly interpreted the complex phenomenon in terms of excited states in nuclei.

Later on we find Rutherford using both protons and deuterons to probe the structure of nuclei although he frequently reverts to the use of his beloved α-particles. At the end of his life he was searching for the mass-3 isotopes of hydrogen and helium.

Many of the papers reproduced in the volume are classic examples of scientific exposition. All students of physics would benefit greatly from reading them. It is not usually possible to find time to search out the originals so we are greatly indebted to the late Paul Rosbaud, who inspired Sir James Chadwick to collect together all of Rutherford's written work into this invaluable series of volumes, which are a truly worthy monument to his work as a physicist.

C. C. BUTLER

Weltkarten zur Klimakunde

Von H. E. Landsberg, H. Lippmann, KH. Paffen und C. Troll. Zweite auflage. Herausgegeben im Auftrage der Heidelberger Akademie der Wissenschaften von E. Rodenwaldt und H. J. Jusatz. Pp. viii+28+5 Weltkarten. (Berlin: Springer-Verlag, 1965.) 30 DM.

THE title page, contents list, foreword and text of this publication are presented in both German and English; a pocket at the back encloses five world maps (scale 1 : 45,000,000, equal area projection) of January sunshine, July sunshine, annual sunshine (hours), annual total of global (that is, direct plus diffuse solar) radiation (cal cm^{-2}) and 'seasonal climates of the earth'. There is not, therefore, a lot of new information for 30 DM, but it must be conceded that the printing and binding are of the highest quality.

The maps are intended, in conjunction with an atlas of epidemic diseases already published, as a contribution to medical meteorology, a subject which has traditionally excited more interest in German- than in English-speaking circles, both medical and meteorological. It is hard to see how such relatively small-scale maps, necessarily displaying only very generalized isolines, can advance the subject much, though it no doubt ill becomes a non-medical meteorologist to say so. The maps are, of course, authoritative. Dr. Landsberg, who is director of climatology in the United States Weather Bureau, is responsible for those of solar radiation and contributes a terse note on radiation climatology. Prof. Troll, of the University of Bonn, is meticulous, though verbose, in explaining his

classification which is the basis of the climatic map. The whole of the information can be found elsewhere without too much difficulty; the book is a well-made luxury.

G. D. ROBINSON

Plasticization and Plasticizer Processes

A Symposium sponsored by the Division of Industrial and Engineering Chemistry at the 147th Meeting of the American Chemical Society, Philadelphia, Pa., April 6–7, 1965.) (Advances in Chemistry Series, No. 48.) Pp. ix+200. (Washington, D.C.: American Chemical Society, 1965.) 7 dollars.

PLANS for considerable increases in production capacity for polyvinyl chloride announced by manufacturers in Britain will be accompanied by similar increases in plasticizer output and interest in both plasticization and the production of plasticizers, and makes the publication of this book timely. It includes specialist papers of both a review and an experimental nature on a number of different aspects of the subject, which were presented at a symposium in the United States in 1964. Its title is, therefore, perhaps misleading since it is not a reference book. Unlike a number of other books published in recent years it is international in character, papers being presented from five different countries. These cover the theory of action of plasticizers; although it is clear that the user will still have to make his choice of plasticizer largely by means of empirical tests. Esters still predominate as plasticizers, and there are some interesting papers discussing recent developments of interest to the manufacturer of plasticizers, in particular further work on the production of ester plasticizers directly from olefins, and also the use of amphoteric type catalysts in esterification. Other papers include a review of polymeric plasticizers, analytical aspects and some highly specialized papers of rather limited interest. This book is probably the most authoritative to appear since the publication of Doolittle's book in 1954 and will be of considerable value to research workers who are interested in either the production of plasticizers or in obtaining a greater understanding of the action of plasticizers. It is reasonably priced.

R. J. WICKER

Heat Transfer in Structures

By H. Schuh. (International Series of Monographs in Aeronautics and Astronautics, Vol. 7.) Pp. xviii+338. (Oxford, London and New York: Pergamon Press, Ltd., 1965.) 70*s*.

THE author has set out to strike a balance between the interests of all workers in the heat-transfer field and the special interests of those in the field of aeronautics. Although his examples are taken wholly from aeronautics, *Heat Transfer in Structures* is certainly of considerable interest to a wider public.

After dealing with external heat-transfer to structures in high-speed flight, and the fundamental laws for heat-transfer within structures, the author deals separately with (*a*) analytical, and (*b*) numerical methods of calculation for (1) steady, and (2) transient heat flow. He finishes the work with a discussion of heat flow in particular structural elements, the use of analogues, the similarity laws and model testing for heat flow in structures.

Complex shapes, found in other fields such as turbine rotors and casings, and steam header pipes, are not mentioned. It is as well to remember while reading the book that the applications discussed are, on the whole, applications to simple shapes. This must be particularly borne in mind when assessing the justification for the author's happy conclusions regarding the small errors in his calculations.

Nevertheless, the author's approach is a fundamental one and everyone has much to learn. Many problems common to aeronautical and other fields are discussed, and particularly interesting are the effects of the flight plan on heat-transfer and his comparison of the effects of the modes of heat-transfer.

RUSSELL HOYLE

Impeller Pumps

By Stephen Lazarkiewicz and Prof. Adam T. Troskolański. Pp. xiv+648. (London and New York: Pergamon Press, Ltd.; Warsaw: Wydawnictwa Naukowo-Techniczne, 1965.) 120*s*. net.

IMPELLER Pumps is a good book, well written and well translated. The authors, one an eminent consulting engineer, the other a distinguished teacher, have revised and enlarged their first book, which was in Polish. Prof. S. P. Hutton has written the preface. The volume is an excellent treatise and book of reference for student, designer, draughtsman, consultant and contractor. Comprised of twenty-three chapters with 506 figures, the book deals with theory and design practice, installation and maintenance. Worked examples demonstrate methods where necessary and each chapter has a list of references which show that the authors have used books from ten different countries.

Diagrams, figures and printing are excellent. Proof reading has been good—there are few printers' errors—and a useful list of symbols is provided. Acknowledgment is made to thirty-nine pump-makers who have contributed to the book in some fashion; nineteen of these are British. Name index and subject index are adequate, although I feel that the latter might have had broader coverage. Centrifugal, mixed-flow, diagonal and propeller pumps are discussed in detail. Attention is given to hydraulic side-thrusts, volutes, recuperators and diffusers of all types, and reference is made to peripheral and water-ring pumps.

Quite properly, the authors have a large chapter on fundamental theory of impeller flow. The longest chapter of all is that dealing with pumps for special duties, such as pumped storage, boiler-feed, corrosive liquids, solids in suspension, etc. Constructional and design details are given for castings, balancing, sealing-rings, stuffing-boxes, shaft sizes, bearings, sudden temperature changes, etc. Much space is allotted to discussing impeller flow, number of blades and choice of blade angles. Dynamical similarity and scale-model tests are fully discussed, as well as full-scale and air testing. The sections on self-priming, pump driving, pump–pipeline systems and discharge regulation are useful, but little or no space is given to water-hammer or surge problems in connexion with complete impeller head–discharge characteristics.

Modern theories of cavitation phenomena are clearly expounded and in a long chapter on cavitation the authors give a full and lucid explanation of net positive suction head or, as they prefer to call it, anti-cavitation pressure margin. The book ends with a short section listing common faults in pump operation and how to correct them.

Undoubtedly, coming as it does from the authors' own experience, this volume is a welcome addition to the literature on the growing science of pump design.

A. S. THOM

Science of Ceramics

Proceedings of the 2nd Conference held under the auspices of the British Ceramic Society and the Nederlands Keramische Vereniging, at Noordwijk aan Zee, May 1963. Edited by G. H. Stewart. Vol. 2. Pp. 431. (London and New York: Academic Press, Inc., 1965.) 84*s*.

SCIENCE of Ceramics records the papers presented at a joint meeting of the British and Dutch Ceramic Societies held in Holland in 1963, which was the second of a series planned by the two societies to provide opportunities for the exchange of views and information in the rapidly growing and peculiarly challenging field of ceramics. The

book contains twenty-eight papers, of which twenty-one are in English, four in German and three in French. Eleven of the papers are by British authors.

The first group of papers includes an important account of the characteristics of fine oxide powders (down to below 100 Å) and a 'new look' at kaolinitic clays which challenges X-ray and differential thermal analyses and proposes an ingenious, simple alternative method of estimating the nature and proportion of clay mineral in a kaolinitic clay. The second group covers process problems: one paper deals with the principles of comminution and another with compaction of powders. A study of torsional hysteresis in plastic clay throws new light on 'plasticity'.

The third group, covering behaviour during the firing process, presents a number of papers on sintering, ranging from the dynamic properties of grain boundaries to the effect of atmosphere. The final group covers structures and properties, and ends with a short survey of glass-ceramics. Another paper deals with solid solutions of certain oxides which can be used as solid-state electrolytes.

While the general reader must not expect to get from this book a coherent picture of ceramic science and technology, he will be provided with a wide sample of some of the problems, and at the same time the specialist will find a good deal of useful material here. The book is well produced and well documented, and one looks forward to the steady progress of this new series. N. F. ASTBURY

Annual Survey of Organometallic Chemistry

Vol. 1. Covering the Year 1964. By Dr. Dietmar Seyferth and Dr. R. Bruce King. Pp. viii+330. (Amsterdam, London and New York: Elsevier Publishing Company, Ltd., 1965.) 110*s*.

THE annual review type of literature is one of the most useful forms of secondary research source: it suffers from a disadvantage in that the work reported is disjointed and undigested, but has the great advantage that this is red-hot from the journals. Even the lack of digestion is sometimes an advantage; it does not impose a point of view and chance scraps of information or chance juxtapositions can be very evocative of new ideas.

The primary literature in the rapidly growing field of organometallic chemistry can be very confusing, and an annual survey such as this performs a real service. In order to systematize the subject, it is divided according to the periodic table, but with a separation of main group metals from transition metals. The form of presentation is similar to the staccato one familiar to readers of the *Annual Reports* of the Chemical Society, but coverage is far more extensive and there is a welcome abundance of formulae. The aim has been to pick significant contributions, and although this is clearly a subjective matter, the authors appear to have performed their herculean task with skill and industry.

Whether for browsing by inorganic or organic chemists who are just interested in a general way, or as an entry into the literature for research students, this book, and no doubt its successors, will be worth having on the bookshelf. A. J. BIRCH

Introducing the Insect

By Prof. F. A. Urquhart. Pp. x+258. (London: Frederick Warne and Co., Ltd., 1965.) 30*s*. net.

IT is difficult to know what to say in fair comment on *Introducing the Insect*. It opens with the words: "This book is designed for the beginner . . . ", and on this basis it should be judged. It certainly qualifies in simplicity, clarity and directness. The style is conversational, without being jocular, slangy or journalistic. The text is clearly arranged, broken into short sections with headings in bold type, and no time is wasted by either the writer or the reader in getting to the point. There are keys to orders and to families, and plenty of simple, clear drawings.

The author is a professional entomologist of international standing, known for his detailed studies of the Monarch butterfly. Entomologically, therefore, the book is sound, and much of the information comes from the author's own experience. In fact what the book says is admirable; it is what it omits that causes misgiving.

The keys provide an example of this. Pages 34–37 discuss how to use a key, and as an example a simple key is constructed to four types of screws and nails. "You can see how easy it is to use identification keys, and how helpful they are." This works satisfactorily so long as you know that there are only four items, and that your choice must be one of these, but how far would anyone get who took such a little key into an ironmonger's shop? All the keys in the book suffer in like manner. An incomplete key to orders, omitting those that are 'obscure', is probably justified, and is helped out by the generally excellent little drawings. But is the reader really helped by: "17. Antennae usually thread-like or feebly clubbed; usually found feeding on leaves of plants. *Leaf-eating Beetles*" (p. 155)?

The function of any book of instruction is not only to give the reader information, but also, and equally important, to leave him clearly aware of the limits of his knowledge. The most serious criticism of the present book is that it does not do so; that, indeed, the formal arrangements of keys and text gives a misleading impression of near-completeness. This book does not compare in quality with the books of the "Wayside and Woodland" series by the same publisher, which are listed on the back of its book-jacket. HAROLD OLDROYD

The Coccidian Parasites (Protozoa, Sporozoa) of Rodents

By Norman D. Levine and Virginia Ivens. (Illinois Biological Monographs, No. 33.) Pp. 365 (48 plates). (Urbana, Illinois: University of Illinois Press, 1965.) 8.50 dollars.

THIS book should certainly be in the library of every parasitological department. Its authors are well known throughout the world for their research on, and wide experience of, the coccidian parasites, not only of rodents, but also of birds and other hosts as well. Well and clearly written, and illustrated by copious figures assembled in forty-eight plates which are either photographs or very clear line drawings and two text-figures, all of which together show clearly the diagnostic features of the species of coccidia described, the book considers and defines 176 species of the genus *Eimeria*, nine species of the genus *Isospora*, one species each of the genera *Caryospora*, *Dorisiella*, *Wenyonella klossia* and *Tyzzeria*, two species of the genus *Cryptosporidium* and three of the genus *Klossiella*. The characteristics of the species of these genera found in rodents are summarized in Tables 1–29. Table 31 gives the characteristics of the species of the genus *Eimeria*, and Table 32 summarizes the results of cross-infection experiments carried out with species of *Eimeria* found in rodents. The extensive list of references to the literature adds greatly to the value of the book, which is beautifully produced and is printed on glossy paper throughout, the whole production reaching the high standard we have learned to expect from these publishers. Every parasitologist will agree that the authors have performed a great service by writing this book. G. LAPAGE

Brave New Victuals

An Inquiry Into Modern Food Production. By Elspeth Huxley. Pp. 168. (London: Chatto and Windus, Ltd., 1965.) 21*s*.

MRS. HUXLEY'S new book deals in the usual old victuals. Although it is sub-titled *An Inquiry Into Modern Food Production*, it covers everything from factory farming to fall-out, and takes in hormones,

insecticides and chemical weed-killers *en route*. In short, it examines all the 'unnatural' procedures, except artificial insemination, which have recently been deliberately or accidentally introduced into modern farming. While the book says nothing new, it does summarize most of the arguments for and against intensive farming and the uses of chemicals in food production, in fifteen concise and reasonably up-to-date chapters. There are some minor errors of fact, and some of the references in the chapter-by-chapter bibliography are too incomplete to be of use to the lay reader.

The book betrays its origins as a series of articles in *Punch*, not only because each topic gets nearly equal treatment, but also because clarity of presentation is often sacrificed to journalism. ("Were *they* happy? Who knows? The crated calves I saw did not *look* unhappy . . .", may involve the reader emotionally, one way or the other, but it scarcely helps understanding.) Intensive animal husbandry has been more rationally, and more effectively, considered in the recent report of the Brambell Committee[1].

The journalistic approach also oscillates between recognizing the need to be modern and 'with it', and the appeal of supporting the 'natural' order. So, while the need to meet food shortages is recognized, a bias towards old-fashioned techniques tends to show through and discussion of pros and cons becomes clouded. There are no suggestions about acceptable alternatives, and no detailed analyses of the reasons why accountants are taking over from farmers: the book is descriptive rather than constructive. Not surprisingly, then, it concludes with a mystical discussion ("Is what is wrong, sheer numbers?") and ends with the suggestion that the missing factor in our approach to food production is charity: the computer, calculating profitability, cannot fit love into the farming equation.

Differential and Riemannian Geometry

By Prof. Detlef Laugwitz. Translated by Fritz Steinhardt. Pp. xii+238. (New York: Academic Press, Inc., ; London: Academic Press, Inc. (London), Ltd., 1965.) 68*s*.

DIFFERENTIAL and Riemannian Geometry is a translation of the 1960 Teubner book, *Differentialgeometrie*. Its main feature is that it combines an account of classical differential geometry (of curves and surfaces) with an introduction to the tensor calculus and Riemannian geometry. It is a refreshing text, among books in English on the subject, because it contains various results not usually found in English texts. Among these special mention might be made of the results on curves and surfaces in the large, given in the final chapter.

A short first chapter on the local geometry of space curves is followed by one on surfaces. The tensor calculus and Riemannian geometry are then introduced. The next chapter commences with an account of spaces of constant curvature and non-Euclidean geometry. After a section on mappings there is an interesting and important discussion on Riemannian spaces and analytical dynamics. Finally there is a section on the characterization of Riemannian geometry.

In the final chapter, on differential geometry in the large, considerable use is made of Herglotz's method of integral formulae. The four vertex theorem is proved, and also Fenchel's theorem that for every closed space curve, the total curvature is at least 2π (and is 2π only for plane convex curves). These results are followed by theorems on surfaces in the large.

For a fairly extended honours course in differential geometry this book would be most stimulating. It contains more than one hundred and fifty exercises and many references to original papers. There is a short appendix on the history of differential geometry and another appendix on some relevant theorems of analysis.

L. S. GODDARD

The Measurement of Efficiency of Scientific Research

By Dr. Ben-Ami Lipetz. Pp. xv+262. (Carlisle, Mass.: Intermedia, Inc., 1965.) 7 dollars.

THE main purpose of this book is to clarify the meaning of efficiency in scientific research and to indicate specific approaches by which the efficiency of such research could, in practice, be measured with the view of increasing productivity. The book is refreshingly free from jargon, for the most part it is well written and its lucid argument supports its emphasis on the importance of clear writing in publications on research. It is, moreover, thoroughly pragmatic and the author shows himself well aware of the essential factors in creativity research and the problems that confront the administrator. He recognizes, for example, that the effective utilization of manpower is one of the most acute problems, and that while there has been little or no improvement in the efficiency of scientific research, improvement must come essentially from the administrator's own hard-won experience. Dr. Lipetz's criticism of methods proposed for evaluating or comparing some contributory methods is sound but, nevertheless, rejecting the idea that any research project is unique in its objectives and achievements and therefore beyond comparison, he proceeds to outline possible procedures for comparison.

This is done in successive chapters on the validity and limitations of the efficiency concept, the recurrent products of scientific research, the objective measurements of scientific achievement and measurements of the scientific content of communications and the problems presented. For his purpose, he relies essentially on a comparison of the reports or scientific publication resulting from the research, in spite of the admitted difficulties to which he frankly directs attention. For all the clarity of the exposition of the need or desirability for some comparison of scientific research, the author is not convincing in his account of how in practice this is to be done, and the latter part of the book disappoints the expectations aroused by his initial aproach. There are ample references which cover the limited literature reasonably, and there is a good bibliography, but the book deserves an index.

R. BRIGHTMAN

The World of Learning 1965–1966

Sixteenth edition. Pp. xiv+1442. (London: Europa Publications, Ltd., 1965.) 140*s*. net.

THE sixteenth edition of *The World of Learning* contains classified information on the universities, colleges, learned societies, libraries, museums, art galleries and research institutes of 158 countries. The new edition is not greatly increased in bulk but has been considerably extended by the use of three columns to a page for the greater part of the university and college sections. This has enabled the editors to include more than 1,500 institutions not previously listed, 625 of which are in the United States. Other features include an up-to-date account of the United Nations Educational, Scientific and Cultural Organization and a section dealing with the International Council of Scientific Unions. The sections on universities and colleges give details of the professorial staffs, rectors, registrars, librarians and deans of faculties, and include list of publications and details of the numbers of students. The sheer bulk of this volume bears witness to the spread of cultural and especially scientific activity at a high level throughout the world. This book now has an honoured place as a guidebook to world scholarship, and the editors and publishers are to be congratulated on the careful presentation and arrangement of their material.

(*Continued from page 44*)

In the case where the pattern of behaviour as a two-host tick was displayed, some of the larvae that had been experimentally fed did not drop off from the rabbit at all. They moulted into nymphs at their feeding sites. The nymphs also fed but when fully replete they dropped off on the dates shown in Table 3 (*a*).

Table 4. LARVAL TO NYMPHAL STAGE FEEDING SITES OF *Boophilus decoloratus* (KOCH, 1844)

No of mother tick	Date of infesting host	Sites of the host at which engorged nymphs were observed										
		Head	Ear		Eyelid		Back	Neck		Nose	Flanks	
			Left	Right	Left	Right		Left	Right		Left	Right
268	25.5	—	—	—	—	—	—	7	9	—	—	—
1	19.6	—	5	1	4	2	—	—	—	5	—	—
5	24.8	—	11	10	—	—	35	—	—	—	10	15
	Total	—	(27)		(6)		(35)	(16)		(5)	(25)	

The adults bred from the above stock of nymphs could not attach to the rabbit for more than 2 days when attempts were made to feed them on the ear of this animal.

When the host's body was gently stroked in order to locate the small engorged larvae several such immature individuals were dislodged at the same time. It was therefore not easy to make specific quantitative observations on the predilection sites for the engorged larvae. However, most of these seemed to drop from the trunk region of the host. Table 4 (*b*) shows the distribution of the engorged nymphs on the body of the rabbit. It will be seen that the head region, including the ears, the area around the eyes, and the nose appeared to be most heavily infected by the nymphs.

The water dropping from the feeding bottle in the ventilated cage and the urine of the confined rabbit maintained a relative humidity inside the cage as high as 90–95 per cent. In spite of this condition and the apparently favourable laboratory temperature range, it was remarkable that throughout the breeding experiments no larvae were able to develop continuously through the nymphal stage into engorged adults on the body of the rabbit; this is especially remarkable because tick species of the genus *Boophilus* are noted for their one-host type of life-cycle[1–5].

The earlier record from Ghana of atypical behaviour of *B. decoloratus* as a two-host tick species was with reference to its principal domestic host, the ox[1]. This contribution would seem to record for the first time two patterns of atypical behaviour in this tick species on the rabbit, namely, a three-host type and a two-host type of behaviour.

As *B. decoloratus* is a one-host tick, the hosts of its larvae are the same as those of the adults[2]. Hoogstraal[2], Tromsdoff[6] and Bedford[7] have listed hares (*Lepus* sp.) among the wild hosts of *B. decoloratus*. Both the hare and the rabbit belong to the same order—Lagomorpha[8]. It is possible that the atypical patterns of behaviour displayed by this tick species on the rabbit could occur unnoticed in Nature, in the case of the hare.

I thank the Ghana Academy of Sciences for enabling me to undertake this work at the Animal Research Institute.

ROLE OF PLANT GROWTH IN REGULATING PHOTOSYNTHESIS

By G. B. SWEET and PROF. P. F. WAREING
Department of Botany, University College of Wales, Aberystwyth

IT has long been known that the rate of photosynthesis is one of the more important factors affecting plant growth and that any external conditions affecting the photosynthetic process will, as a consequence, affect growth. It is only comparatively recently, however, that evidence has been put forward to suggest that growth itself can affect the photosynthetic rate, and that instead of there being a one-way relationship, photosynthesis → growth, there may, in fact, be an interrelationship, photosynthesis ⇌ growth.

Went[1] postulated that in some circumstances the rate of photosynthesis might be limited by growth rate, and suggested that a slow rate of translocation of photosynthates out of leaf cells could limit the rate of carbon dioxide reduction. This hypothesis has since been supported by the work of Hartt[2], who found a reduction in the rate of photosynthesis of detached sugar cane leaves following exposure to light of saturating intensity, the decrease in photosynthetic rate being associated with a build-up in sucrose-levels. Similarly, Humphries and Thorne[3], working with detached leaves of dwarf beans growing in nutrient solution, found an increase in the rate of photosynthesis associated with increased translocation following development of roots from the petiole. Such experiments, although not carried out on whole plants, do support the possibility that in whole plants the rate of growth may itself directly affect photosynthesis, by affecting the rate of removal of assimilates from the production areas.

An experiment using whole plants gives further evidence in this direction. Thorne and Evans[4] inter-grafted in all possible stock–scion combinations sugar beet which has a large storage root and a high net assimilation rate with spinach beet having a smaller storage root and a lower net assimilation rate. Grafts with sugar beet roots had a greater net assimilation rate than grafts with spinach beet roots, irrespective of the type of scion used. The results were interpreted to suggest that sugar beet roots increased the net assimilation rate (and thus net photosynthesis) of scions grafted on to them by providing a more efficient 'sink' for assimilates than spinach beet roots, thus again implying a direct effect of growth on photosynthesis.

An experiment with apple trees by Maggs[5], involving part removal of leaves, roots, or leaves and roots in combination, showed that growth rate and net assimilation rate were affected by these treatments. A change in net assimilation rate implies a change in rate of net photosynthesis, and if, as seems likely, the treatments did not affect the rate of photosynthesis directly, the results again imply an effect of growth on photosynthesis.

So far as we are aware, the experiments described here are the first in which direct measurements of photosynthesis have been made on whole plants in order to investigate an alteration in photosynthetic rate caused by a change in internal growth conditions and to examine the mechanics of this change.

Experiment 1. 16-month-old seedlings of *Pinus radiata* grown in compost in 4-in. pots were used for the experiment, which was carried out in December 1964. At this time, while the plants had not formed winter buds they were making slow growth only. Three treatments were applied. In each of these, the plant apex (including all primary needles which had not fully elongated) was removed. The treatments differed only in the time interval between removal of the apex and measurement of photosynthesis, these intervals being as follows:

Treatment 1	8 days
Treatment 2	16 days
Treatment 3	No time interval. This treatment constituted the control.

The plants in series 1 made no obvious new growth between treatment and measurement of photosynthesis, but those in series 2 produced new needles from the primary leaf axils during that period.

Rates of uptake of carbon dioxide by the plants were measured at four different light intensities by infra-red gas analysis using an open-circuit system. Each replicate of each treatment consisted of two plants the roots of which were washed clean of soil and placed in plastic containers of water in the assimilation chamber. The experiment was run with air from outside the laboratory, brought up to a temperature of 20° C and a relative humidity of 80 per cent. The light source was a 6,000 W high-pressure xenon lamp.

Results of net carbon dioxide uptake are presented for the treatments in Fig. 1. Because of the difficulty of measuring leaf area in pines, the data have been expressed as units of carbon dioxide uptake per unit of leaf dry weight per unit of time. Differences were significant at the 1 per cent level.

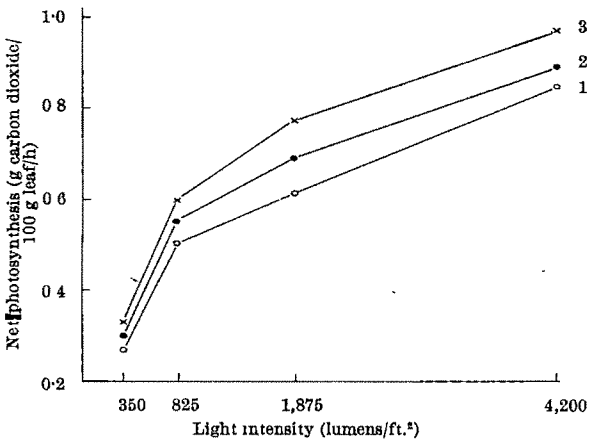

Fig. 1. Rates of net photosynthesis for 16-month-old seedlings of *Pinus radiata* with the plant apex removed The time interval between removal of the apex and measurement of photosynthesis was as follows: series 1, 8 days; series 2, 16 days, series 3, no time interval. Treatment differences are significant at the 1 per cent level

Fig. 1 shows that treatments 1 and 2 gave a decrease in rate of net photosynthesis compared with that of the controls (treatment 3). This decrease was greatest at high light intensities and least at low light intensities. Treatment 1 depressed the net rate of carbon dioxide uptake more than did treatment 2.

Each of the three treatments resulted in removal of the same proportion of leaves from the plants, the only difference between treatments being in the time interval between removal of the apex and measurement of photosynthesis. It is clear, therefore, that the treatment itself could have had no direct effect on the rate of net photosynthesis. Rather, the rate of photosynthesis must have been affected by the changes in internal growth conditions, which probably included the following: (1) A reduced overall 'sink' for assimilates as compared with the controls; (2) a reduced auxin-level in the plants compared with that of the controls.

If either of these changes did, in fact, cause a limitation in the rate of photosynthesis, the effect should have been reduced when new growth commenced after treatment. The plants of series 2 did show new growth prior to measurement of photosynthesis and, in fact, their rate of net carbon dioxide uptake at the time of measurement showed a reversion to a position mid-way between that of series 1 and of the controls. Thus the postulated result was observed.

Experiment 2. Actively growing 11-week-old seedlings of *Pinus radiata* grown in compost in polythene bags were used for this experiment, and four different treatments were applied to them.

Treatment 1	All fully expanded leaves removed 6 days before measurement of photosynthesis.
Treatment 2	One-third of the fully expanded leaves removed 6 days before measurement of photosynthesis.
Treatment 3	All fully expanded leaves removed immediately prior to measurement of photosynthesis.
Treatment 4	Controls. No leaf removal.

Rates of carbon dioxide uptake of the plants were measured as in Experiment 1. However, this time each replicate in each treatment consisted of five plants, and measurement was made at six different light intensities. In addition, respiration rates in the dark were determined. The results are presented in Fig. 2.

It is apparent that treatments 1 and 2 caused a significant increase in the rate of net photosynthesis over that of the controls (treatment 4). This increase was not very great at low light intensities, but at saturating light intensity it was very pronounced, the increase in net photosynthetic rate of treatment 1 over that of the controls being 27·4 per cent. The plants of treatment 3, from which fully expanded leaves were removed immediately before measurement of photosynthesis, showed essentially the same photosynthetic rate as those of the controls, and

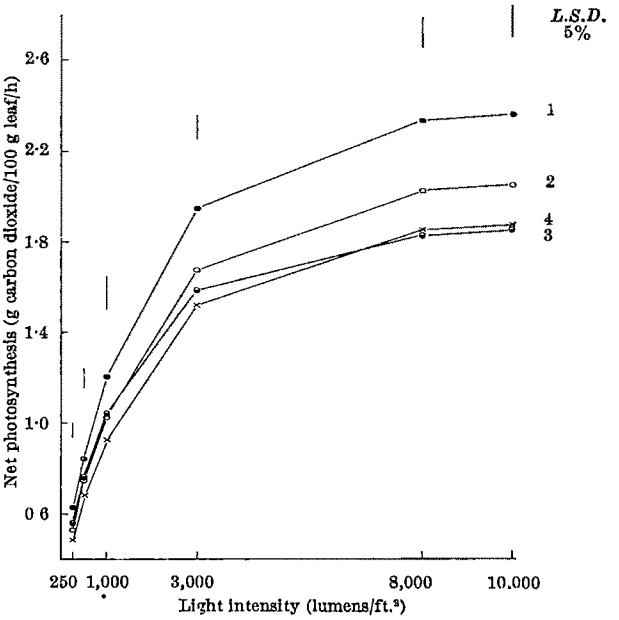

Fig. 2. Rates of net photosynthesis for 11-week-old seedlings of *Pinus radiata* with four treatments applied as follows: series 1, all fully expanded leaves removed 6 days before measurement of photosynthesis; series 2, one-third of the fully expanded leaves removed 6 days before measurement of photosynthesis; series 3, all fully expanded leaves removed immediately prior to measurement of photosynthesis; series 4, no leaf removal. Treatment differences are significant at the 0·1 per cent level

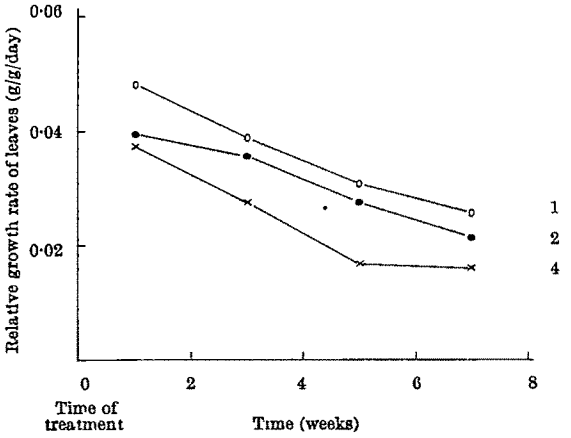

Fig. 3. Changes in leaf relative growth rate with time for three series of *Pinus radiata* seedlings. At time 0, series 1 had all fully expanded leaves removed and series 2 had one-third of the fully expanded leaves removed. Series 4 with no leaf removal formed the control. Treatment differences are significant at the 0·1 per cent level

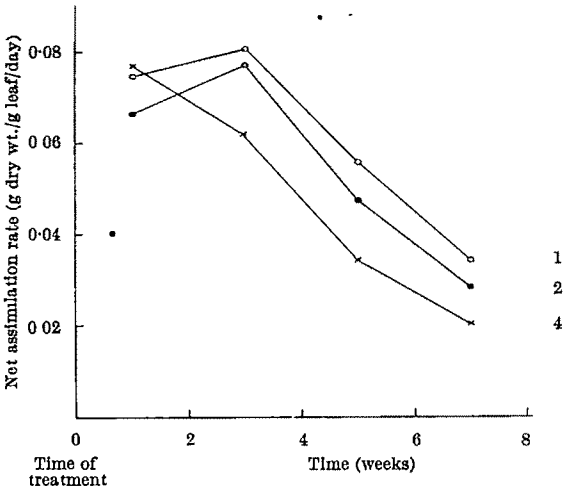

Fig. 4. Changes in net assimilation rate with time for three series of *Pinus radiata* seedlings. At time 0, series 1 had all fully expanded leaves removed and series 2 had one-third of the fully expanded leaves removed. Series 4 with no leaf removal formed the control. Treatment differences are significant at the 0·1 per cent level.

treatments 1 and 3, which differed only in the time of leaf removal, caused significantly different photosynthetic rates at every light intensity.

There was no significant difference between the plants of the four treatments in dark respiration rate expressed on a whole plant basis. As the treatments differed in the ratio, weight of photosynthesizing tissue : weight of total respiring tissue, it is not valid to compare respiration rates calculated on a leaf basis, or gross photosynthesis expressed per unit of leaf tissue. However, the lack of significant difference between treatments in respiration rate of the whole plants makes it clear that the pattern of gross photosynthesis for the treatments was essentially the same as that shown for net photosynthesis.

The significant differences between series 1 and 3 indicate that, as in experiment 1, the observed effect must have been an indirect one, with the treatments affecting the internal growing conditions of the plants, and thus, in turn, the photosynthetic mechanism.

That the treatments also affected the growth of the plants was shown by a growth analysis experiment carried out on plants treated in the same way as those for which photosynthetic rates were measured. Results of this are shown in Figs. 3 and 4. The treated plants had both a higher relative growth rate of the leaves (Fig. 3) and a higher net assimilation rate (Fig. 4) than the controls, both differences being significant at the 0·1 per cent level. Eight weeks after treatment, the rates of relative leaf growth and net assimilation rate showed little sign of reverting to the level of the controls.

The treatments, removal or partial removal of fully expanded leaves, have with time had two obvious effects on growth of the plants, namely: (1) While leaving the actively growing 'sink' for photosynthates comparable with that of the controls, they reduced the photosynthesizing area of leaf. If, as shown by Maggs[5], leaves normally operate at levels well below the maxima of which they are capable, such an effect might be expected to increase the photosynthetic activity of the remaining leaves. (2) They have increased the relative growth rate of the leaves compared with that of the controls. This could be expected to increase further the 'sink' for photosynthates, and might also be expected to increase the auxin production of the treated plants, since young leaves appear to produce higher levels of auxin than mature leaves.

Thus, as in experiment 1, the reason for the change in the rate of photosynthesis may lie either in a 'metabolic sink' effect, or in an effect of auxin-level on the rate of photosynthesis. In support of this latter possibility, Turner and Bidwell[6] have demonstrated an increase in the photosynthetic rate of bean leaves following spraying with indolyl-3-acetic acid (IAA) solution. This increase was smallest at low light intensities, but was markedly greater towards saturation light intensity, a pattern which parallels that shown in the two experiments reported here. They interpret their results as an effect by IAA on some mechanism which normally limits the rate of the dark reaction in photosynthesis.

At this stage it is not possible to state with certainty whether the auxin or the 'metabolic sink' interpretation is correct, or whether the two may be interrelated in their effect. Davies and Wareing[7] have shown that in *Pisum sativum* IAA applied to a decapitated stem stimulated the movement of phosphorus-32 from a lower part of the stem to the locus of application where it accumulated, and that this effect was apparently independent of growth. It seems possible, therefore, that the movement of metabolites out of leaves may also be to some extent under auxin control. Humphries[8] stressed that where rates of photosynthesis were limited by a reduced 'sink' for metabolites, the factor limiting photosynthesis was not the build-up of photosynthates *per se*, but rather the reduction in the rate of translocation from the leaves. It is possible, therefore, that although the reported changes in photosynthetic rate have been caused by a change in the rate of movement of metabolites out of the leaves, this movement has in turn been affected, at least partially, by the auxin-level in the plants.

Certainly much more work is necessary before the mechanism involved can be understood with any certainty. What is clear, however, is that the rate of photosynthesis in *Pinus radiata* seedlings is in some part subject to control by the growth of the plants, and that photosynthetic behaviour can be altered by manipulation of internal growth conditions. Rates of photosynthesis can either be increased or decreased by such means. The fact that rates of photosynthesis can be increased to well above normal levels should be of interest to plant breeders, and it is likely that with further knowledge of the processes involved, it may be possible to tap this unused potential for the production of faster growing plants.

This work was carried out while G. B. Sweet was on study leave from the New Zealand Forest Service, Forest Research Institute, and in tenure of a David Henry scholarship.

LETTERS TO THE EDITOR

RADIO ASTRONOMY

Low-frequency Spectrum from Radio Source 3C84

RECENTLY, Roger *et al.*[1] reported some measurements of the flux densities from the discrete source 3*C*84 at two frequencies—10·03 Mc/s and 22·2 Mc/s. These and measurements reported by other research workers[3,4] were used to plot the radio spectrum of 3*C*84 in the frequency range 10–10^4 Mc/s.

Roger *et al.* reached the conclusion that the source 3*C*84 (which has been identified as the Seyfert Galaxy NGC 1275 (ref. 2)) has an unusual spectrum both at high and low frequencies. They commented that the spectrum of the source 3*C*84 has a slope of about -2 at the frequencies $-f > 20$ Mc/s, instead of $-0{\cdot}7$ at the frequencies 10^2 Mc/s $\leqslant f \leqslant 3 \times 10^3$ Mc/s; moreover, they found an anomaly in the radio spectrum range 10–20 Mc/s.

In earlier publications[5,6] we described some measurements of flux densities of the source 3*C*84 on frequencies 20, 25, 31 and 38·5 Mc/s. Flux densities were measured relative to Cassiopeia-*A*(3*C*461), and the absolute calibration of the radio telescope system was made at seven frequencies for Cassiopeia $-A$ in the frequency range 12·5–40 Mc/s (ref. 7). The slope of the spectrum of 3*C*84 for frequencies from 20 Mc/s to 150 Mc/s was found to be $-1{\cdot}15$ (Fig. 1).

For $f \geqslant 150$ Mc/s, flux densities were taken from ref. 8.

It can be seen from Fig. 1 that the flux density for 3*C*84 at 22·2 Mc/s as given in ref. 1 fits the spectrum with a slope of $-1{\cdot}15$.

It should be pointed out, however, that the flux density given by Roger *et al.* for 3*C*84 at $f = 10{\cdot}03$ Mc/s is incorrect. As an absolute calibration of the system was not available at 10·03 Mc/s, they used the flux densities measured relative only to 3*C*274 (Virgo-*A*), and the flux density of 3*C*274 was obtained by linear extrapolation of the measured values from very high frequencies. But it is well known[7] that for Virgo-*A* the flux density, S_D, is almost constant in the region from $f = 35$ Mc/s to $f = 12{\cdot}5$ Mc/s; moreover, $S_D \approx 5 \times 10^{-23}$ Wm^{-2} (c/s)$^{-1}$ (ref. 7) and not $S_D \approx 10^{-22}$ Wm^{-2} (c/s)$^{-1}$ as given by Roger *et al.* Thus the flux density of 3*C*84 at $f = 10{\cdot}03$ Mc/s must equal $(490 \pm 170) \times 10^{-26}$ Wm^{-2} (c/s)$^{-1}$, that is, half the value given by them.

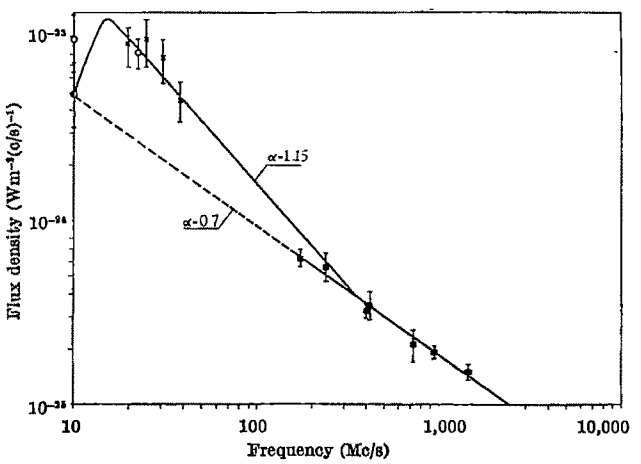

Fig. 1. Radio spectrum of source 3*C*84. ×, Flux densities from refs. 5 and 6; O, flux densities from ref. 1

All the experimental points fitted a smooth solid curve and the shape of the spectrum of 3*C*84 can be seen in Fig. 1. Between 10 and 20 Mc/s there is a sharp change in slope and the curve becomes very steep.

It is obvious that the exact shape of the spectrum of 3*C*84 in the frequency ranges 10–20 Mc/s and 50–150 Mc/s is unknown: it will be necessary to make many further measurements before the spectrum of 3*C*84 is established.

GEOPHYSICS

A Helium Whistler observed in the Canadian Satellite *Alouette* II

LIKE her sister *Alouette* I, the *Alouette* II satellite carries a broad band, very-low-frequency receiver, but the pass band has been extended to (0·05–30 kc/s) from (0·4–10 kc/s). The *Alouette* II orbit has almost the same inclination as that of *Alouette* I ($\sim 80°$), but is elliptical with a perigee of 501 km, and an apogee of 2,983 km, rather than the almost circular 1,000 km orbit of *Alouette* I. One of the significant discoveries made by analysis of very-low-frequency data recorded by the *Alouette* I satellite[1] was that an atmospheric (an electromagnetic impulse originating from a lightning flash) that had propagated upwards to the satellite was often immediately followed by a novel type of very-low-frequency signal. Initially, the frequency of this signal rose rapidly; the rate of increase then gradually diminished until the frequency approached a nearly constant value. These signals have been termed proton whistlers, and analysis[2] has shown that they are due to coupling of wave energy from the (electron) whistler mode into ion cyclotron waves. Such coupling is possible only at frequencies below the proton gyro-frequency. The coupling occurs over a range of heights below the satellite, with a given frequency component coupling most strongly at a height determined solely by the positive ion composition of the ionosphere. The resulting ion cyclotron waves propagate upwards to the satellite and suffer increasing time delay as their frequency approaches the local proton gyro-frequency. This interpretation explains the form of dispersion exhibited by proton whistler signals, and why such signals are observed only after the occurrence of a normal short fractional hop whistler as well as the manner in which the wave energy enters and propagates through the lower ionosphere.

At the time that this interpretation of the proton whistler was developed it was realized that a similar phenomenon might occur in the vicinity of the helium gyro-frequency. However, none of the very-low-frequency

receivers that were in orbit at that time had sufficient sensitivity at low frequencies to detect signals at or below the helium gyro-frequency. In order to determine whether helium whistlers could be detected, the very-low-frequency receiver of the *Alouette* II spacecraft was designed so that it would be sensitive down to frequencies of about 50 c/s. On one of the first *Alouette* II very-low-frequency records from the southern hemisphere, proton and helium whistlers were both observed (see Fig. 1). Analysis of this signal has shown that it is not a particularly good example of a short fractional hop whistler nor of a proton whistler, but it is the best example of the several helium whistlers obtained during this pass. The temporal variation of the helium whistler frequency is of the same form as that of the proton whistler and the values of gyro-frequency derived from the helium and proton signals are in the ratio 4 : 1 to an accuracy of about 0·2 per cent.

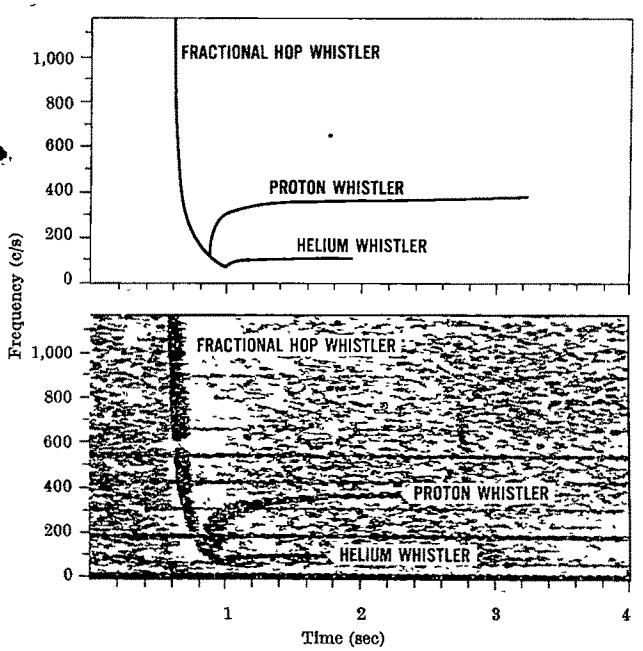

Fig 1. A proton and helium whistler observed in the *Alouette* II satellite. The lower part of the figure shows the spectrum of this signal as produced by a 'Sona-Graph' spectrum analyser The upper portion of this figure is an idealized representation of this event Ororal, Australia, December 3, 1965, 1221.15 U.T., 132° E. long , 32° S lat., 2,007 km height

It has been shown[3] that the frequency variation of a proton whistler can be used to determine the number density of protons in the vicinity of the satellite. In a similar manner the number density of helium ions can be derived from the frequency variation of a helium whistler. The helium and proton whistlers of Fig. 1 have been analysed in considerable detail to yield the number density of protons and helium ions at the satellite. The frequencies at which the proton and helium whistlers separate from the (electron) whistler signal are termed 'cross-over' frequencies and depend only on the fractional abundances of the positive ions comprising the medium[2]. The two cross-over frequencies of the whistler signals shown in Fig. 1 were measured, and used to derive the relative abundances of O^+, He^+ and H^+ ions. In determining the abundances of these ions, it was assumed that they are the major constituents of the ionosphere at the satellite height. The results of this analysis are summarized in the following:

	H^+	He^+	O^+
Number density	6.5×10^3/c.c.	270/c.c.	—
Fractional abundance	0·89	0·038	0·07

From the number density and relative abundance of H^+ the electron number density was found to be $7{\cdot}3 \times 10^3$/c.c. Since independent determinations of the number densities and fractional abundances of H^+ and He^+ are made, two measures of the ratio $n(He^+)/n(H^+)$ can be calculated. The ratio of the number densities of these ions is 0·042 and the ratio of their fractional abundances is 0·043, indicating quite good agreement between the different methods of measuring this ratio. It is highly significant that, in the atmospheric region where this event was observed, O^+ was more abundant than He^+ in spite of the fact that H^+ was by far the dominant constituent. These facts suggest that if an approximation to diffusive equilibrium exists during this measurement, then He^+ must be a relatively minor constituent of the ionosphere at all heights at this time and place.

In summary it can be stated that the simultaneous observation of proton and helium whistlers provides a direct and accurate means of measuring the composition and electron density of the ionosphere at great heights above the Earth's surface. Since these parameters are determined from a radio propagation phenomenon of large wave-length they are representative of a relatively large volume of the medium at the height in question and are not subject to the difficulties of techniques that directly sense the medium in the vicinity of the spacecraft. The greatest drawback to the very-low-frequency technique is that it depends on a sporadic natural phenomenon, that is, a lightning discharge, which usually produces a short fractional hop whistler, but only occasionally generates ion cyclotron whistlers. In spite of these limitations, the newly discovered helium whistler in conjunction with the proton whistler is a valuable addition to the methods available for studying the high ionosphere.

GEOLOGY

An Estimate of the Rate of Continental Drift in the Permian Period

Continental drift in the Wegenerian sense is now an established theory. Also, it is believed that the supercontinent Gondwanaland itself was drifting around before it was split up. This was suggested by Ahmad[1], on the basis of his study of the glacial deposits in Gondwanaland, although Du Toit[2] had earlier envisaged 'drift *en masse*', without elaborating the point further. The respectability the hypothesis has gained in recent years is, however, due entirely to palaeomagnetic studies[3–6].

The difference between the results obtained by the two approaches is that the path chalked out by Ahmad[1,7], and altered slightly by Ahmad and Ahmad[8], is rather tortuous and complicated. Fig. 1 is based on these. The paths deduced by the palaeomagnetic data, Fig. 2 (ref. 5), are more or less straight, and hence considerably shorter. This is mainly because the latter presumed paths are based upon data for successive geological ages and sometimes longer. What happened in between any two horizons found suitable for palaeomagnetic determinations could not be known.

Also, estimates of the rate of drift have occasionally been attempted on the basis of the palaeomagnetic data[9]. It now appears that a rough idea may be deduced from evidence based on the vicissitudes in the climate of the Salt Range area in the Permian period.

Permian beds, in the area, unconformably overlie the Cambrian System rocks, and are followed by the Triassic beds, without any visible break in sedimentation. The

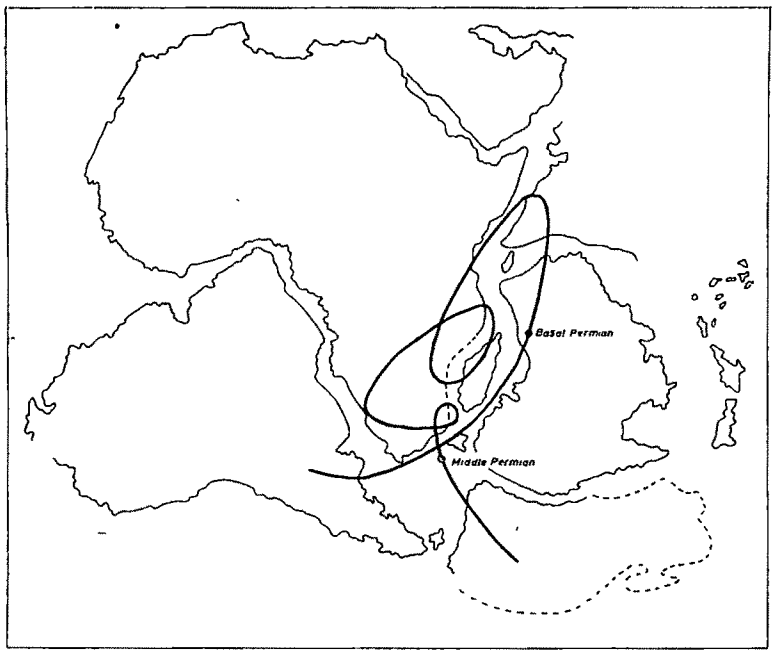

Fig. 1. Probable polar positions in the Lower Permian Period and the route of drift

Boulder Bed at the base of the Permian system is, in places, typically tillitic. Overlying this is the *Eurydesma–Conularia* Bed, 100–300 ft. thick. The lower part of this formation is of continental origin and carries the *Gangamopteris* flora. The *Eurydesma* fauna was adapted to cold climatic conditions and is elsewhere known to occur within the glacial deposits. It entered the area with the first sign of transgression. Considerable time might, therefore, have elapsed between the deposition of the glacial bed and that of the *Eurydesma–Conularia* bed, the two being separated by the fresh-water sediments.

Overlying this bed are 50–100 ft. of barren Lavender Clays and above these come the *Productus* Limestones, carrying a rich and varied fauna. Dunbar studied the fusulines from this horizon and Schuchert[10] concluded that the Upper and Middle *Productus* Limestone fauna indicated a warm, tropical climate. This is also suggested by the richness of the fauna, the deposition of thick, clean, limestone beds, and the presence of reef-building corals. The Lower *Productus* Limestone, however, does not conform to this environmental set-up. The fauna is comparatively sparse and several of the characteristic genera are absent. Schuchert[11] suspected that this sparse fauna, without corals and cephalopods, may indicate that cold waters were holding on. Thus, although it was obviously getting warmer, it was yet not warm enough for the tropical fauna to appear. It came in the Middle *Productus* times. Thomas and Dickins[12] opined that 'A distinct difference also exists between the fauna of the Lower and of the Middle and Upper *Productus* Limestone'. In Western Australia, too, the Lower and Upper Permian faunas have few species in common, and Dickins[13] thought that this indicated 'an important change in the palaeogeographical conditions'.

It therefore seems to follow that, by the end of the Lower *Productus* times, the climate changed from cold and glacial to tropical. If this change was due entirely to a change in the geographical location of the area, it may be placed in about 25° latitude, maybe less. Tillites from polar ice caps are rarely deposited in lower than 60°–65° latitudes, so that the Salt Range area had, in the meantime, moved through about 35° of latitude. It would scarcely be justifiable to assign more than half the Permian period to the deposition of these 700–800 ft. (225–275 m.) of sediments, that is, it might have taken about 25 × 10^6 years. Indeed, even this may be excessive.

A shift of 35° in 25 × 10^6 years means a rate of 0·49 ft. (15 cm) in a year. The figure would be higher if the time taken for the deposition of these beds was less, or if the loops shown on Fig. 1 correctly represent the path of the pole. On the other hand, if it be presumed that the entire Permian succession in the Salt Range was deposited without any significant breaks, and the rate of sedimentation of limestones, shales and sandstones be taken as 1 : 5 : 10, the deposition of *Eurydesma* Bed–Lower *Productus* Limestone would have taken about 17 × 10^6 years. This would mean a rate of drift of about 0·71 ft. (21·3 cm) per year. In contrast Athavale *et al.*[9] estimate a drift of 1·7 cm (0·056 ft.) per year during the last 750 million years. However, accepting even the lower of the two estimated rates of drift given above (15 cm per year), the continents must, then, have been 'sprinting', not just 'drifting'.

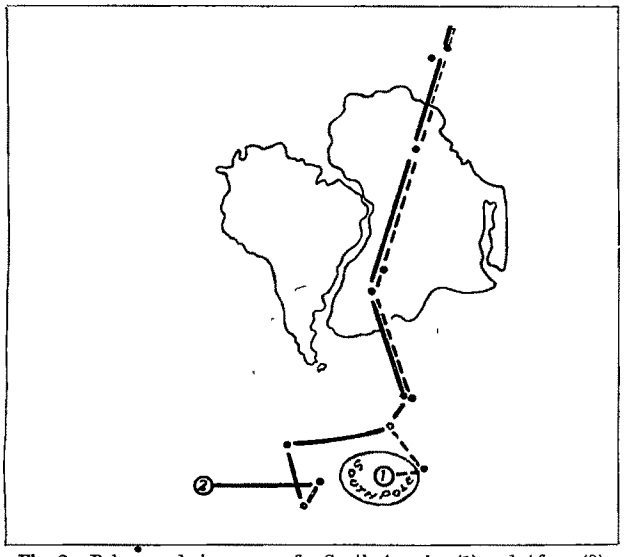

Fig. 2. Polar wandering curves for South America (1) and Africa (2) for Upper Palaeozoic time. (After K. M. Creer (ref. 5))

It, then, seems possible that the widespread occurrence of the Permian glacial deposits was due to the fact that for some reason the rate of continental drift during the Lower Permian period was considerably higher, and consequently widespread areas in different continents came successively under the polar ice cap. If this is accepted, it follows that, whatever might have been the then shape of Gondwanaland, when the Salt Range lay in the tropical belt, South and South-Western Africa must have been in the frigid zone and consequently glaciated, and vice versa. It follows as a corollary that the tillites in different parts of Gondwanaland were not coeval and also that the central part of Gondwanaland must have seen several vicissitudes of climate during the Lower Permian times. Not only is it the case in eastern Australia but the South African Dwyka Tillites may also carry deposits of more than one glacial age[14].

What caused this fantastic rate of drift in the Lower Permian period is not known at present. Stronger convection currents might have been responsible for this, and these, in turn, might have been due to an accumulation of heat in the interior. It is possible that the Hercynian movement, too, formed a link in this chain of events. Escape of heat through volcanic eruptions and

granite emplacements in the mobile belts following the Hercynian orogeny could cause the currents to subside, and the drift to decline.

I thank my colleague, Dr. V. K. Srivastava, for going through the manuscript and offering valuable suggestions.

Loss of Argon from Biotite in a Thermal Metamorphism

ANALYTICALLY, the simplest example of isotope migration in a geological environment is afforded by the loss of radiogenic argon-40 (one of the daughter products of the potassium-40 decay scheme) from minerals in a thermal metamorphism. By suitably selecting the thermal source, and assuming that the argon is lost by a diffusion process having only a single activation energy (E) of argon release, a relatively simple mathematical model of the system can be constructed. The most probable value of E can be deduced by finding for what value of the parameters in the diffusion equation the theoretical argon losses approach closest to those observed. The significance of E is that it affords a convenient numerical criterion for the argon-retentivity of a mineral; the higher the value of E, the more firmly is the argon retained.

The present communication outlines a recent investigation undertaken at the Department of Geodesy and Geophysics, University of Cambridge, into the diffusion of argon from the biotite of a mica schist due to the intrusion of a dyke. The value of E inferred from the diffusion process using the foregoing approach is compared with that obtained in complementary laboratory experiments, with the same biotite, on the kinetics of argon release in a vacuum.

For the geological investigations, a 20-ft. Tertiary dyke was selected in the pelitic Moine Schist area in the East of the Ardnamurchan peninsula, Argyllshire, Scotland. Samples of the schist were taken at the contact and at various distances along in a line perpendicular to the strike of the dyke. The apparent potassium/argon ages of the biotite separated from these samples within 10 ft. from the dyke were found to decrease regularly from the accepted value of 420 m.y. for the Moine Schist to about 100 m.y. at the contact.

For the mathematical treatment, several idealized models of a cooling dyke were considered[1]. In each case, the dyke was visualized as an infinite flat sheet, and the schist as having uniform composition on either side of the dyke. Computations of the temperature distributions resulting from these models showed that the incorporations of a latent heat raised contact temperatures by about 100° C relative to models without it, but that the way in which the latent heat was liberated was unimportant. Consequently, the mathematically simplest case of a dyke evolving its latent heat of solidification (80 cal g^{-1}) entirely at its temperature of intrusion (1,150° C) was adopted for calculations of the theoretical distributions. The thermal conductivities, densities and specific heats of the schist and solidified basalt were taken to be identical (0·005 cal cm^{-2} sec^{-1}; 2·7 g cm^{-3}; 0·22 cal g^{-1}, respectively)[2,3].

The biotite flakes were assumed to have lost argon by radial diffusion, involving a simple exponential dependence of the diffusion constant on E and temperature[1], namely, $D = D_0 \exp(-E/RT)$. For computational purposes it is unnecessary to know either D_0 or the average biotite grain radius, 'a', since they occur only as the unit D_0/a^2. However, to guard against the possibility of several combinations of the variable parameters E and D_0/a^2 giving equally good agreement with the observed argon distribution, the range of D_0/a^2 was restricted to the neighbourhood of the value $D_0/a^2 = 1{\cdot}52 \times 10^3$ sec^{-1}; this number was arrived at by taking D_0 to be[4] 0·342 and 'a' to be the average measured biotite grain radius of 0·015 cm.

Fig. 1 (*a*) shows the computed argon retention versus distance from the dyke for various values of D_0/a^2 and E. Distances are in multiples of the half-width of the dyke. Fig. 1 (*b*) compares the observed argon distribution with the theoretical distribution for $E = 40$ kcal/g atom and $D_0/a^2 = 1{\cdot}52 \times 10^3$ sec^{-1}.

Out of interest, the foregoing model was modified to correspond to the geological conditions met in a similar, but independent, investigation by S. R. Hart in Colorado[5,6]. Fig. 2 shows that for $E = 40$ kcal/g atom, $D_0/a^2 = 12{\cdot}0$ sec^{-1}, reasonable agreement is obtained between theory and observation (compare $E = 16$ kcal/g atom inferred by Tilton and Hart[5]). The departure of theory from observation in both cases may reflect some over-simplification in either the thermal or the diffusion model; or in both. Laboratory experiments on the kinetics of the release of argon from biotite when heated *in vacuo*[7] do, in fact, show that the loss of the bulk of argon is associated not with one, but two activation energies. Below 800° C, the release appears to be described by a cylindrical volume diffusion model having $E \simeq 35$ kcal/g atom, and above 800°

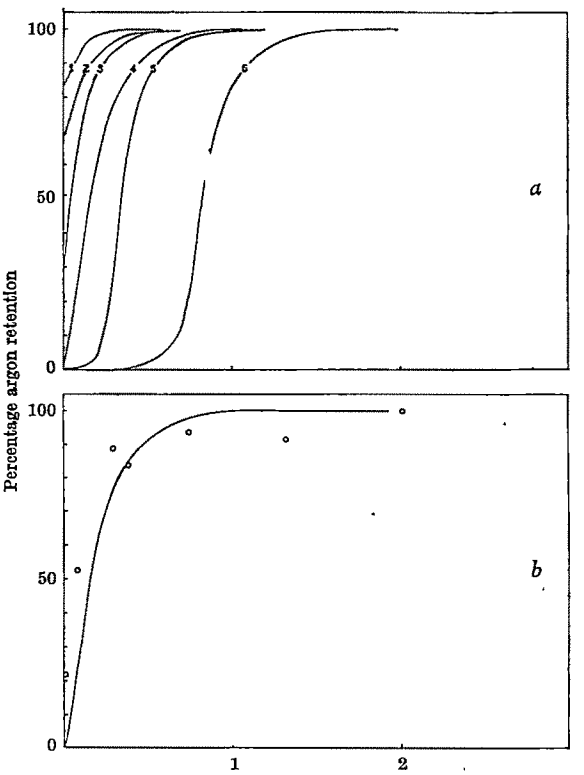

Fig. 1. *a*, Argon retention (theoretical). (1) $E = 48$, $D/a^2 = 1{\cdot}52 \times 10^3$; (2) $E = 48$, $D/a^2 = 3{\cdot}8 \times 10^2$ (3) $E = 48$, $D/a^2 = 0{\cdot}95 \times 10^2$; (4) $E = 40$, $D/a^2 = 1{\cdot}52 \times 10^3$; (5) $E = 40$, $D/a^2 = 0{\cdot}95 \times 10^2$; (6) $E = 30$, $D/a^2 = 1{\cdot}52 \times 10^3$. *b*, Comparison of observed distribution with theory ($E = 40 \times 10^3$ cal/g atom, $D_0/a^2 = 1{\cdot}52 \times 10^3$ sec^{-1})

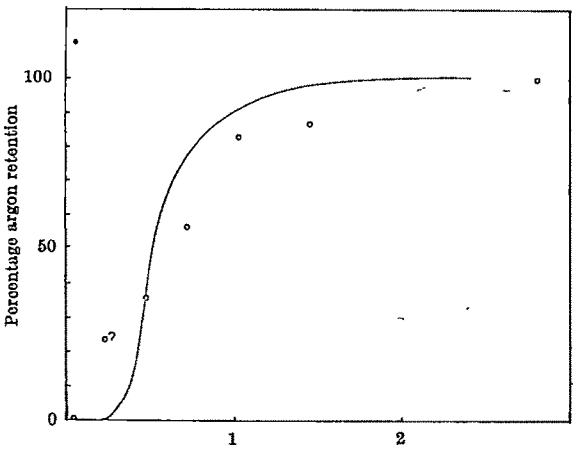

Fig. 2. Comparison of Hart's (1963) results with theory ($E = 40 \times 10^3$ cal/g atom, $D_0/a^2 = 12{\cdot}0$ sec^{-1})

C by such a diffusion mechanism with $E = 49$ kcal/g atom.

These results are of further interest in that they show a close agreement between a laboratory-determined E for a mica, and one inferred from the effects of a thermal metamorphism on isotopic ages. From the available values of E, it would appear that a laboratory value is usually higher than one determined geologically (Table 1).

PHYSICS

Laminar Plasma Jets in Nitrogen

VARIOUS authors[1-3] have reported that under certain conditions the high-temperature jet issuing from the throat of a direct-current plasma torch can be given a laminar form and extended from its normal length of a few centimetres to about one metre. This communication describes some results of a series of experiments in which the development and structure of laminar jets in nitrogen have been studied with the aid of schlieren and spectroscopic techniques.

The structure of the jet produced at the outlet of the throat (diameter 3 mm, length 1 cm) of an experimental plasma torch[4] at a current of 100 amp and a gas flow rate of 20 l./min is shown in Fig. 1. Region I extends as a cone 5 mm in length, over which distance it produces spectral lines, in varying intensity, of tungsten (W) and of the ionized molecular and excited atomic levels of nitrogen (N^+_2 and N). The presence of tungsten shows that some erosion of the cathode is occurring, while the excitation of the nitrogen levels indicates temperatures in the range from 7,000° K to 11,000° K. Enveloping I is a cone 4 cm long which has a highly turbulent boundary; the spectral lines of tungsten and ionized molecular nitrogen which were observed from the central regions of this cone indicated temperatures from 4,000° K to 7,000° K. Schlieren photographs showed that on slightly reducing the gas flow rate from 20 l./min the turbulent boundary near the throat outlet became laminar although the flow pattern at the jet extremity did not change. On further reduction of the gas flow rate, the length of the laminar boundary increased so that the turbulent regions at the jet extremity moved increasing distances from the throat outlet; at 8 l./min they were at a maximum distance, for the present experimental arrangement, of 45 cm. The structure of the jet produced at this gas flow rate is shown in Fig. 2. The length of region I is about 1 mm, one-fifth of that in the normal form of the jet. Region II is 12 cm long and produces from its central regions spectral emission of tungsten and ionized molecular nitrogen; only spectral lines of tungsten are produced from the central regions of region III. The expansion of the jet from 3 mm (diameter) at the throat outlet to 1·5 cm in the laminar flow at the onset of the turbulent termination region was not constant, the diameter increasing to 8 mm over the first 12 cm corresponding to the length of region II.

Other experiments[4] have shown that in the normal form of the jet (Fig. 1), the gas flowing through the throat of the plasma torch extends the arc column into a 'hairpin' form. This extension continues until the voltage drop along the column becomes greater than the breakdown potential between the column and the throat

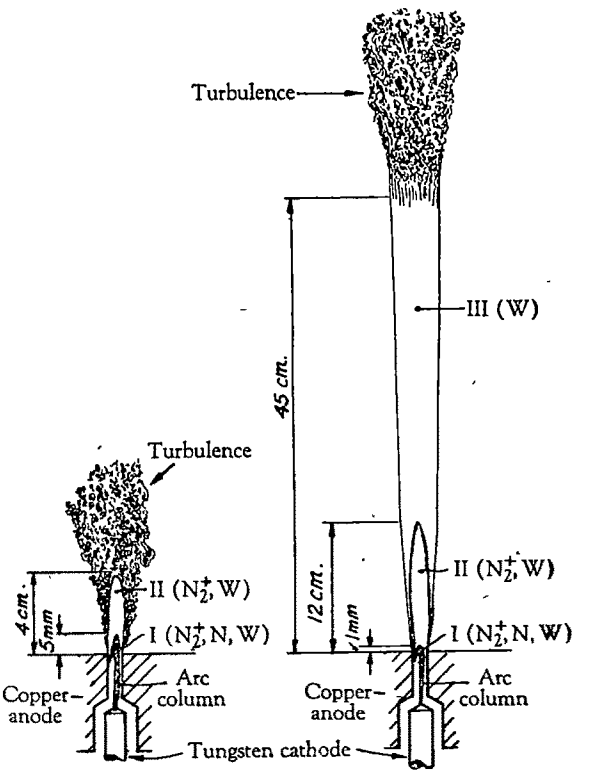

Fig. 1. Normal jet structure (20 l./min)

Fig. 2. Laminar jet structure (8 l./min)

(anode), so that the column short-circuits to the throat. This process of lengthening and short-circuiting repeats itself continually at an amplitude and frequency dependent upon the current and gas flow rate and is revealed in the arc voltage developed in the torch which exhibits a saw-tooth waveform.

In the laminar jets investigated in these experiments, the arc voltage fluctuated in this manner, suggesting that the arc column process of continual lengthening and short-circuiting is also present in this form of jet. The amplitude and frequency of the saw-tooth voltage fluctuations in the laminar jets always tended to be lower than those measured, at the same current, in the normal jets. For example, in a 100 amp jet in its normal form (Fig. 1) the voltage fluctuation had an amplitude of 22 V and a frequency of 23 kc/s, while the fluctuation produced at the same current when the jet was in its laminar form (Fig. 2) had an amplitude of 7 V and a frequency of 12 kc/s. This reduction in amplitude and frequency with gas flow rate is similar to that reported previously[4]. The decrease in the length of region I with the reduction in gas flow rate, and the observations from this region of spectral lines of atomic nitrogen, suggest that it contains the maximum extension of the main conduction path of the arc column.

To determine whether the development of the laminar jet is dependent upon the Reynolds number of the emergent gas, the gas enthalpy was derived from the measurement of the temperature rise and flow rate of the cooling water. The known enthalpy-temperature relation for nitrogen[5] was then used to determine the mean gas temperature and thus the density, viscosity[6] and, from the gas flow rate, the mean velocity. In turbulent form (100 amp, 29 l./min) the emergent gas had a mean temperature of 6,600° K and thus the density (ρ) of $5{\cdot}2 \times 10^{-5}$ gm/c.c., viscosity (η) $1{\cdot}6 \times 10^{-3}$ poise, velocity (U) $1{\cdot}1 \times 10^{5}$ cm/sec, and using the expression

$$\text{Reynolds number} = \frac{Ud\rho}{\eta}$$

where d is the throat diameter (3 mm), a Reynolds number of 1,040. In laminar form (100 amp, 8 l./min), the gas temperature of 7,100° K gave density, viscosity and velocity of $4{\cdot}8 \times 10^{-4}$ gm/c.c., $1{\cdot}8 \times 10^{-3}$ poise and $4{\cdot}6 \times 10^{4}$ cm/sec, respectively, and a lower Reynolds number of 368. This dependence of the jet form on the Reynolds number is similar to that reported for diffusion flames[7] in which the turbulent region terminating the laminar flame was observed to move increasing distances from the burner outlet with decreasing Reynolds number. The turbulent termination region was thought to be due to friction in the boundary layer between fuel and air, causing changes in the viscosity and density of the flame. Similar boundary layer phenomena may be occurring in laminar jets. Further investigations will be concerned with this aspect and will involve measurements of the velocity and temperature changes produced in these jets in the region of the laminar flow below the turbulent termination region of the jet.

Mechanism of Viscous Flow in Water

BY treating viscous flow, self-diffusion and dielectric relaxation as rate processes, it has been shown that in water the energies of activation associated with the foregoing processes not only exhibit the same temperature dependence but have identical values[1,2]. The dielectric relaxation time τ of a polar liquid has been expressed in terms of the viscosity η by the Debye equation:

$$\tau = \frac{4\pi a^3 \eta}{kT} \qquad (1)$$

where a is the molecular radius. Equation (1) does not hold for hydrogen-bond-associated liquids (such as 2-methyl heptan-3-ol and octan-1-ol)[3], yet it holds for water, and the value of $a = 1{\cdot}4$ Å obtained from a plot of τ^{-1} against η/T agrees well with recently published data[4]. The foregoing findings can be explained with the aid of the 'flickering cluster' model for water, described by Frank and Wen[5], on the basis that the time taken for a translational jump or a molecular re-orientation is less than the mean life-time of the clusters, which may be of the order of 10^{-11} sec. Thus, in a discussion of viscous flow, the nature and concentration of non-hydrogen-bonded water must be considered a major factor. This is made possible by using the cluster model of Nemethy and Scheraga[6]. For ease in computation the clusters are taken to be spherical and, from a consideration of their total area and volume, the x_i parameters (mole fractions of i-bonded water) are calculated as functions of temperature. The molar volume of water, V_{H_2O}, is the sum of the volume of clusters, V_b, and the volume of dipolar water, V_u, and it is given by:

$$V_{H_2O} = (x_0 + x_1)\, V_u + (x_4 + x_3 + x_2)\, V_b$$

(In this representation of the molar volume of water lies one of the main differences between this model and that proposed by Frank and Quist, in whose gas hydrate type structures unbonded water molecules can only fill vacant sites in the clusters and therefore cannot contribute to V_{H_2O} (ref. 10).)

where V_b can be taken to be the extrapolated molar volume of ice, and V_u can be calculated at each temperature from a knowledge of x_i, V_{H_2O}, and V_b.

Thus on a time scale of 10^{-11} sec liquid water can be treated as a suspension of incompressible spheres in a dipolar fluid of viscosity η_0, and as a first approximation the viscosity of such a suspension can be written as:

$$\eta = \eta_0 (1 + 2{\cdot}5\, \varphi_b) \qquad (2)$$

where φ_b is the volume fraction of clusters. φ_b was obtained as a function of temperature, by using the calculated values for x_i, V_u and V_b, and hence η_0 was obtained at each temperature. An Arrhenius plot of log η_0 against $1/T$ was linear above $\sim 40°$ C but showed a curvature, convex to the $1/T$ axis, below that temperature. Since equation (2) is a limiting equation, it was concluded that at lower temperatures φ_b became too large for this equation to hold. Accordingly, two other equations were used to calculate η_0:

$$\eta = \eta_0 (1 + 2{\cdot}5\, \varphi_b + 7{\cdot}35\, \varphi_b^2) \qquad (3)$$

and

$$\eta = \eta_0 (1 + 2{\cdot}5\, \varphi_b + 7{\cdot}17\, \varphi_b^2 + 16{\cdot}2\, \varphi_b^3) \qquad (4)$$

Equation (3) has been applied to concentrated suspensions[7], and equation (4) also allows for the effect of binary encounters of suspended spheres on the viscosity of the suspension[8]. When plotting log η_0, as obtained from equations (3) and (4), against $1/T$, linear relationships were again obtained above $\sim 40°$ C, although with somewhat smaller slopes than that given by equation (2). The results obtained from equation (4) are shown in Fig. 1. The values of η_0 are of the same order of magnitude as are the viscosities of other dipolar, non-associated liquids. The energy ΔH_η, and entropy, ΔS_η, of activation are 1,400 cal. mole^{-1} and 1·0 e.u., and these values approx-

imate closely to those obtained for liquid ammonia and sulphur dioxide. By inserting the value for η_0 in equation (1), the relaxation time τ_0 of unbonded water can be estimated; at 40° C this is found to be 1×10^{-12} sec. This value is consistent with the assumption that the rate-determining process is the decay of the hydrogen-bonded clusters, and that compared to this the time required for the secondary process is small.

In order to confirm that the nature of the results shown in Fig. 1 was not fortuitous, the viscosity data were also tested against the water model of Wada[9]. This postulates a simple equilibrium between ice-like and monomeric species. According to Wada's calculations, x_b decreases from 0·42 at 0° C to 0·20 at 100° C. From a knowledge of ΔH^0, the enthalpy change associated with the formation of the ice-like species from the monomeric species, the equilibrium constant, and hence x_b, could be obtained over the temperature range 0°–100° C. The derived η_0 values, obtained with equation (4), are included in Fig. 1 and it is seen that here again the unbonded water appears to behave as a normal fluid above ~ 40° C. Since the structural model of Wada is based on very different premises from that of Nemethy and Scheraga, we may conclude that the results are not restricted to a particular formalism adopted in the development of the structural model and in the calculation of x_b (T), but that they do apparently reflect a property of liquid water.

In order to calculate the effect of pressure on the transport properties of unbonded water, its compressibility, β_u, must be known, as well as $(\partial x_u/\partial P)_T$, where $x_u = (x_0 + x_1)$. Assuming that ideal mixing occurs between clusters and unbonded water:

$$-\frac{\Delta V^0}{RT} = [x_u\,(1 - x_u)]^{-1}\left(\frac{\partial x_u}{\partial P}\right)_T \qquad (5)$$

where $\Delta V^0 = V_u^0 - V_b^0$. Following Nemethy and Scheraga, the compressibility of liquid water can be written as:

$$\beta_{H_2O} = -(V_{H_2O})^{-1}\,[x_u(\partial V_u/\partial P)_T + x_b(\partial V_b/\partial P)_T + \Delta V^0(\partial x_u/\partial P)_T] \qquad (6)$$

For β_{H_2O} mean values between 1 and 1,000 atm. were used, and for $(\partial V_b/\partial P)_T$ the compressibility of ice at 0° was used. Values for the term $(\partial x_u/\partial P)_T$, included in the structural contribution to β_{H_2O}, were obtained using equation (5). Knowing $(\partial V_u/\partial P)_T$ and $(\partial x_u/\partial P)_T$, φ_b was calculated as a function of temperature, and hence η_0 could be obtained for water under a pressure of 1,000 atm. It was found that the particular model gave reasonable results up to 60° C; above this temperature $(\partial V_u/\partial P)_T$ increased with rising temperature.

The calculated viscosities of unbonded water at a pressure of 1,000 atm. are included in Fig. 1. It can be seen that a plot of linear log η_0 against $1/T$ is again obtained above 30° C, but that at lower temperatures the deviations from the linear relationship are not as pronounced at 1,000 atm. as they are at 1 atm. As is the case for normal fluids, a rise in pressure leads to an increase in the viscosity of unbonded water, and also to an increase in ΔH_η (1·5 kcal. mole^{-1}). From the pressure coefficient of ΔH_η, the volume change of activation, ΔV_η, is found to be + 5 c.c. mole^{-1}, which again is of the right order of magnitude for a non-associated liquid with a molar volume of 16 c.c. mole^{-1}.

All curves in Fig. 1 show that at low temperatures $\Delta C_{p\eta}$ is negative and it approaches zero between 30° C and 40° C, that is, at the temperature at which C_p for liquid water passes through a minimum.

On the basis of the formalism adopted in the interpretation of the viscosity of water, above ~ 35° C the results are consistent with the cluster model which allows for an unbonded species acting as a normal dipolar fluid. Below 35° C a temperature-dependent ΔH_η indicates that this model is not valid.

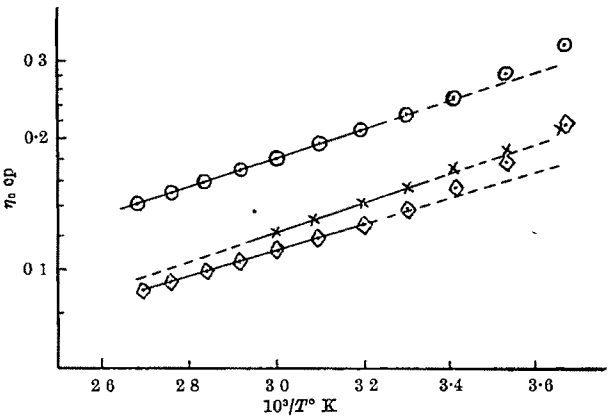

Fig. 1. Viscosity of unbonded water, as given by equation (4), and based on the structural models of Wada (ref. 9) (○) and Nemethy and Scheraga (ref. 6) (◇, at 1 atm., ×, at 1,000 atm)

It is therefore reasonable to conclude that at low temperatures the interstitial model may provide a more realistic representation of the state of liquid water, that is, unbonded molecules can exist only as guests inside a quasi-crystalline framework[10]. With rising temperature, however, x_b decreases, and a physical limit of this model is set by the condition $x_b < \nu/(\nu + 1)$, where ν is the number of molecules in the structural species which are required for the provision of each interstitial site. Frank and Quist have pointed out that, as x_b approaches this limiting value, another species (State III) must provide the predominant contribution towards the observed properties, and they state that the temperature at which this occurs may well be in the region of 35° C.

The results show that this "State III" may well consist of the same two species but that a transition from a quasi-crystalline structure to a suspension of clusters in a dipolar fluid takes place, so that the thermodynamic state of the unbonded water undergoes a change.

Such a transition in the region of 35° C may be responsible for the reported discontinuities shown by many physical properties in aqueous systems, for which there is an increasing amount of evidence[11,12].

Determination of Radial Distribution Functions by Elastic Electron Diffraction

THE ordering of matter in amorphous materials can be characterized by a radial distribution function of density $4\pi r^2 \rho(r)$, and a difference radial distribution function $4\pi r^2(\rho(r) - \rho_0)$. The latter is obtained[1] from experimental scattering data $I(s)$ by the Fourier inversion:

$$4\pi r^2\,(\rho(r) - \rho_0) = 8\pi r \int_0^\infty s\left(\frac{I(s) - f^2}{f^2}\right)\sin\,[2\pi r\, s]\,ds$$

where $s = 2\sin\tfrac{1}{2}\beta/\lambda$, β is the scattering angle, and f is the

atomic scattering factor. f is a smoothly decreasing function of s and the quantity to be inverted is the ratio of the ripple of $I(s)$ about $f^2(s)$, to the smooth curve $f^2(s)$.

Attempts have been made to obtain the radial distribution function using electron scattering. These attempts have always used the total scattered electron intensity $I_t(s)$, from which electrons scattered inelastically were not removed. We have recently measured both the filtered intensity $I_f(s)$ and the total intensity $I_t(s)$ scattered from a number of materials using the scanning electron diffraction system developed in this laboratory[2–4].

Fig. 1 shows the scattering curve from a thin evaporated carbon film (55 Å thick, 20 kV electrons) with and without removal of loss electrons. The filtered trace contains no electrons which have lost more energy than eV_m, 5 eV. The important differences between the elastic and total intensity curves are: an additional ring at about 0·2 Å^{-1}, three outer rings at s values > 1 Å^{-1}, and true maxima for some of the rings; the unfiltered data (V_m = 20 kV) show no true maxima. The relative ripple values measured in the two cases are therefore very different; when multiplied by the factor s the differences are enhanced. A pronounced difference is obtained between the two radial distribution curves (Fig. 2). The elastic data lead to density functions with greater fluctuation and more order at longer range. Fig. 3 shows marked differences between filtered and unfiltered data from germanium (150 Å film, 20 kV electrons), a fairly heavy element. Grigson and Dove (unpublished) found similar differences in amorphous silicon.

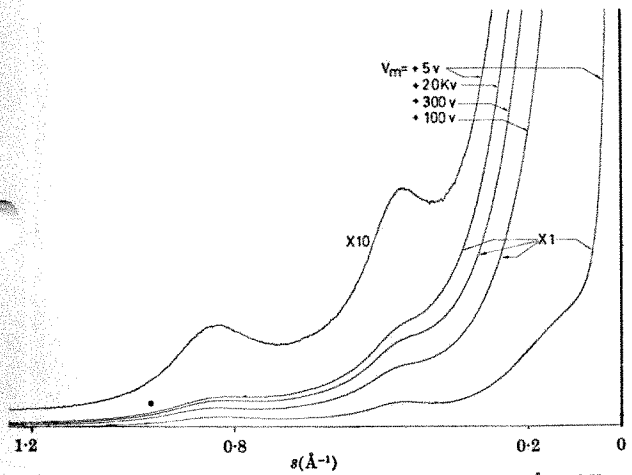

Fig. 1. Filtered and unfiltered scattering curves for carbon, 55 Å, 20 kV

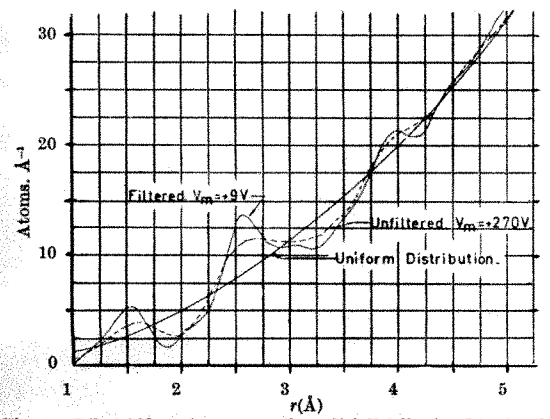

Fig. 2. Effect of loss electrons on the radial distribution function for evaporated carbon, 55 Å, 20 kV, M = 0·1

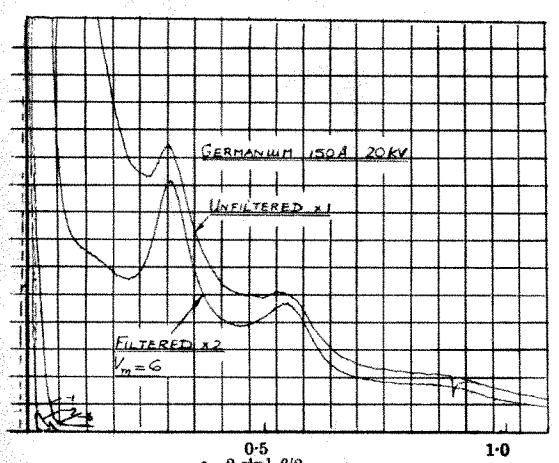

Fig. 3. Germanium, 150 Å, 20 kV

We conclude that unfiltered electron diffraction patterns must not be used for computing radial distribution functions and that when the elastically scattered data are used they are likely to reveal more order at longer range.

CHEMISTRY

Solute–Water Interactions and the Solubility Behaviour of Long-chain Paraffin Hydrocarbons

THE effect of non-polar groups on the structural properties of liquid water is of interest in several fields of enquiry. The most direct method of studying such systems is by the determination of hydrocarbon solubilities, but, until recently, reliable experimental data have been confined to the four lowest members of the paraffin series[1,2]. McAuliffe has provided a valuable extension to the existing data by his study of the solubilities of twenty-three aliphatic and aromatic hydrocarbons[3]. His results show good agreement with earlier data for the C_1–C_4 paraffins[1,2], but his values for the C_5–C_8 members of the series are lower by more than one order of magnitude than the only other recorded solubilities of these hydrocarbons[4].

McAuliffe's results, obtained by a gas chromatographic technique, have recently been confirmed by Baker, who used tritiated and carbon-14-labelled hydrocarbons, in conjunction with a liquid scintillation spectrometer[5]. Baker also extended the scope of his investigation to include the normal C_{10}, C_{18}, and C_{36} paraffins. He found that, although the solubility decreases with increasing chain length, the solubility decrease for each additional CH_2 group is considerably smaller for the long-chain members of the series ($> C_{10}$) than it is for the shorter-chain paraffins.

In order to investigate further this dependence of solubility on chain length, the solubilities of the C_{10}, C_{12}, C_{14}, and C_{16} paraffins were determined at 25° C by gas-liquid partition chromatography[6]. Purum grade (Fluka) hydrocarbons were used; chromatographic analysis indicated levels of impurities (homologues and branch chain isomers) of less than 3 per cent. After equilibrating the hydrocarbon/water mixtures in a thermostat at 25° C [7], up to 0·5 ml. of the aqueous phase was injected into the fractionator fitted to the chromatographic column, and the water was removed by 'Drierite'. The hydrocarbon concentrations were obtained from the peak areas, after initial calibrations, in the usual manner. Replicate determinations indicated an average experimental error of ±12 per cent in the solubilities.

The mean solubilities of the four hydrocarbons, expressed as mole fractions, x, were obtained as follows:

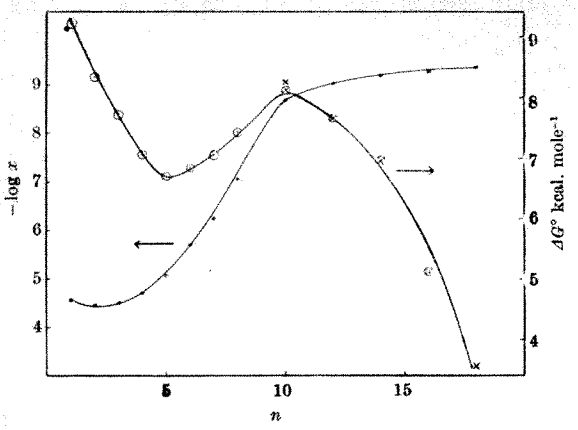

Fig. 1. (Left) Mole fraction solubility and (right) $\Delta G°$ of the norma paraffins as a function of the carbon number n. ○, from ref. 3; ×, from ref. 5; ⊗, this investigation

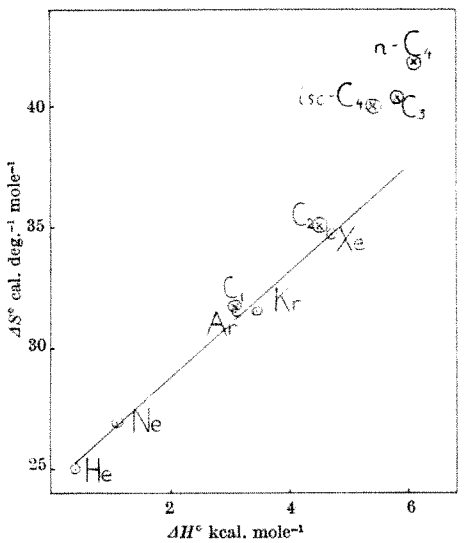

Fig. 2. Barclay–Butler plot for non-polar gases in water. The points for the hydrocarbons are mean values derived from refs. 1 and 2

n-decane $2{\cdot}5 \times 10^{-9}$, n-dodecane $8{\cdot}9 \times 10^{-10}$, n-tetradecane $6{\cdot}3 \times 10^{-10}$, and n-hexadecane $5{\cdot}0 \times 10^{-10}$.

There have in the past been several attempts to express x as a linear function of some property of the hydrocarbons, such as molar volume[8]. McAuliffe points out that a plot of log x against molar volume is linear only for the liquid hydrocarbons. Since the molar volume is a linear function of the carbon number n, it is simpler to plot log x against n, and Fig. 1 shows such a plot for the normal paraffins. It is evident that the linear relationship, if indeed it has any meaning at all, only holds for the C_5–C_{10} members, and the higher members of the series are increasingly more soluble than would be predicted by such a relationship.

A more realistic method of comparing the solubilities of members of a homologous series is to consider the transfer of the solutes from some common standard state to the aqueous solution. Fig. 1 includes a plot of $\Delta G°$, the standard free energy change associated with the transfer of 1 mole of gaseous hydrocarbon at a pressure of 1 atm. to an aqueous solution of a hypothetical unit mole fraction, that is, $\Delta G° = RT \ln (p/x)$, where p is the vapour pressure of the hydrocarbon at a temperature $T°$ K. For the lower members of the series, hypothetical values of p at 298° K were obtained by extrapolation. It is apparent that $\Delta G°$ decreases with n and reaches a minimum for pentane, corresponding to a maximum solubility. The trend is then reversed, and a minimum solubility is observed for decane. For the higher members $\Delta G°$ decreases rapidly with n; this effect is so marked that it would still be apparent, even if the error in the determination of x for, say, hexadecane exceeded two orders of magnitude. The results indicate that the long-chain hydrocarbons are vastly more soluble than would be expected from an extrapolation of $\Delta G°$ values of the lower members of the series. It would be interesting to speculate on the significance of this observation to the properties of lipids in an aqueous environment or to the property of micelle formation which is common to the derivatives of these higher homologues.

Clearly, then, the solubility behaviour of the members of the paraffin series is not as simple as might have been expected; the extrema in the $\Delta G°(x)$ plot probably have their origin in complex enthalpy and entropy effects which are related to the modifications in the structure of liquid water produced by the presence of the solutes. Although, at the present time, $\Delta G°$ data for the higher members ($> C_4$) are available at only one temperature, their nature indicates that the linearity between $\Delta H°$ and $\Delta S°$, which has been observed for different solutes in a given solvent, and which has become known as the Barclay–Butler rule[9], cannot apply to aqueous solutions of hydrocarbons. This already becomes apparent from a consideration of the experimental $\Delta H°$ and $\Delta S°$ values for the C_1–C_4 paraffins[1,2]; Fig. 2 shows that, whereas this rule is valid for a number of simple gases[10], the paraffins increasingly deviate from this linear trend. A fuller discussion of the hydrocarbon solubilities, in terms of water structure, will be published elsewhere.

Preparing Dispersions of Zinc Oxide Particles for Electronmicroscopic Investigation

PARTICLES of a zinc oxide powder cluster together due to the electrostatic forces acting between the individual particles. These clusters can be reduced to a minimum by the technique described here, and a homogeneous distribution of the particles is obtained throughout the sample. This homogeneous distribution is almost a necessity for the investigation of the grain-size distribution of the zinc oxide powder, utilizing microscopic techniques, as it reduces the time involved in the counting procedure.

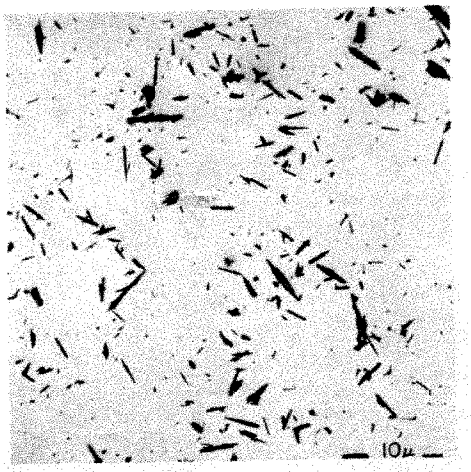

Fig. 1. Needle-shaped particles

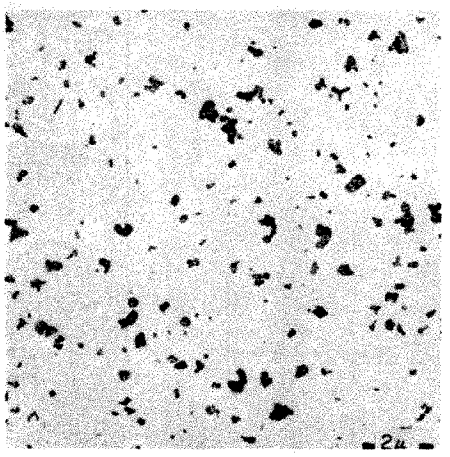

Fig. 2. Particles of different shape (their cross-section is essentially hexagonal)

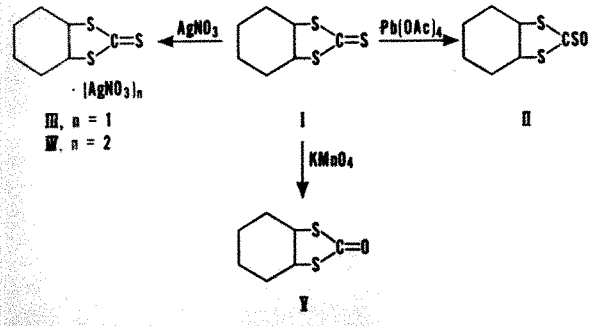
Optimum results were gained when a paste technique was used. The procedure was very simple and the various steps involved were: (1) Zinc oxide powder was placed in a flat agate mortar. The quantity of powder used depended on the shape and the size of the individual particles, but 2·5 mg proved to be satisfactory in most of our experiments. (2) Ten drops of a 0·1 per cent (by weight) solution of 'Formvar' in chloroform were added. The mass was then thoroughly mixed and mulled to the dry state. (3) Step 2 was repeated and in order to extend the time of mixture some pure chloroform was added until the paste was just becoming weak. (4) Twenty drops of the same 'Formvar' solution were added to the paste. After mixing, a drop of the fluid paste was spread out on a glass plate. (5) After drying, the 'Formvar' film in which the zinc oxide particles were incorporated was floated off on a water surface. The film was collected on copper grids and dried. The film was then ready for examination with the electronmicroscope.



The dispersion obtained is not a function of the shape of the particles, as can be seen from Figs. 1 and 2.

Reactions of *Cyclo*hexene Trithiocarbonate with Oxidants

LEAD tetraacetate oxidation of sugar derivatives containing a thiocarbonyl group was shown previously to give the corresponding carbonates, disulphides, or oxythiocarbonyl derivatives, depending on the structure of the parent compound[1]. To determine more fully the effect of oxidants on the thiocarbonyl group, the investigation has been extended to the reactions of *cyclo*hexene trithiocarbonate (I) with lead tetraacetate, silver nitrate, and potassium permanganate.

When I (prepared according to Culvenor *et al.*[2] and dissolved in glacial acetic acid) was treated with lead tetraacetate at 25° C, a rapid consumption of one molecular equivalent of oxidant was observed. The oxidized product (II) was isolated as needles (m.p. 96°–97° C); an analysis of this indicated the addition of one oxygen atom to I (calculated for $C_7H_{10}OS_3$: C, 40·8; H, 4·9; S, 46·2, found: C, 40·8; H, 5·0; S, 45·9).

Compound II gave a negative test with sodium azide[3] for the C=S group. Its ultra-violet spectrum in methanol showed absorption maxima at 347 mμ (ε11,700) and 284 mμ (ε4,900), whereas the spectrum of I had a maximum at 318 mμ (ε14,000). On treatment of a methanol–water solution of II with two molecular equivalents of L-cysteine, the *cyclo*hexene derivative was reduced, and I was recovered in 91 per cent yield and L-cystine was recovered in 92 per cent yield. The reduction of sulphoxides under these conditions has been reported[4,5]. These results are in agreement with the proposed structure of II as being an oxythiocarbonyl derivative of *cyclo*hexene trithiocarbonate. This structure is analogous to that formed on lead tetraacetate oxidation of 1,2-*O*-isopropylidene-5,6-dithio-β-L-idofuranose 5,6-trithiocarbonate[1].

When an acetone solution of I was treated at 25° C with an aqueous solution containing one molecular equivalent of silver nitrate, none of the corresponding carbonate or oxythiocarbonyl was formed. Instead, a crystalline product (III) (m.p. 108°–109° C) was isolated which on elemental analysis showed the addition of one molecular equivalent of silver nitrate to I (calculated for $C_7H_{10}S_3 \cdot AgNO_3$: C, 23·2; H, 3·6; S, 26·6; Ash, 30; found: C, 23·4; H, 2·8; S, 26·0; Ash, 33). The infra-red spectrum of III showed a band characteristic for an ionic nitrate group at 1,390 cm^{-1}, whereas no absorption was found in this region with the parent compound I. The grey adduct product was stable when kept at −5° C but darkened on standing at 25° C for a few hours. This product was insoluble in water, acetone, alcohol and chloroform, but was readily soluble in a mixture of water and acetone or alcohol. Such a solution of III gave no precipitate on addition of diluted hydrochloric acid. However, on treatment of III with 1,2-*O*-isopropylidene-α-D-glucofuranose 5,6-thionocarbonate, silver sulphide rapidly formed along with I and 1,2-*O*-isopropylidene-α-D-glucofuranose 5,6-carbonate.

That the C=S group is not involved in the adduct formation, as has been shown for 1,2-dithiole-3-thione compounds[6], is suggested by a positive sodium azide test for III and by its ultra-violet spectrum which showed an absorption maximum at 318 mμ (ε16,000 in methanol : water 9 : 1 v/v). The spectrum of I had a maximum at 318 mμ (ε14,000 in methanol).

When an acetone solution of I was treated with an excess of silver nitrate, a yellow compound (IV) was obtained as needles (m.p. 144°–146° C) which contained silver nitrate and I in a molar ratio of 2 : 1, respectively. (Calculated for $C_7H_{10}S_3 \cdot 2AgNO_3$: C, 15·8; H, 1·9; S, 18·1; Ash, 40·5; found: C, 15·2; H, 2·1; S, 17·9; Ash, 40·7.) The infra-red spectrum of IV was almost the same as III. The adduct product containing two molecular equivalents of silver nitrate was insoluble in most organic solvents and rapidly decomposed on addition of water. On standing at 25° C, IV was readily decomposed with evolution of acidic vapours.

Presumably the addition of two molecular equivalents of silver nitrate to I is due to the presence of two alkyl sulphide groups since it has been shown[7] that alkyl sulphides combine with 1 mole of silver nitrate to give unstable adduct products.

On reflux of an acetone solution of I with an acetone solution of potassium permanganate the corresponding *cyclo*hexene dithiocarbonate (V) was formed, m.p. 106° C. The course of oxidation was followed spectrometrically, and by the end of the reaction practically no absorption was found at 318 mμ, whereas a strong carbonyl peak

showed in the infra-red region. (Calculated for $C_7H_{10}OS_2$: C, 48·3; H, 5·7; S, 36·8; found: C, 48·2; H, 5·8; S, 36·0.) Razuvaev *et al.*[8] reported the preparation of V by oxidation of I with 60 per cent nitric acid.

Helical Conformation of Poly-γ-benzyl-L-glutamate

RECENTLY, Luzzati *et al.*[1] and Spach *et al.*[2] have suggested that the helical form of poly-γ-benzyl-L-glutamate (PBLG) in dilute solution is that of a $3{\cdot}0_{10}$ helix rather than an α-helix. They reached this conclusion after performing both X-ray diffraction and hydrodynamic experiments on dilute solutions of the polymer in appropriate solvents. They further reviewed the present light-scattering data and concluded that this supported the $3{\cdot}0_{10}$ helical conformation and confirmed the slight flexibility of the helices. They showed that the parameter h, which is the distance between two successive residues projected on to the helix axis or the length of the equivalent rod divided by the degree of polymerization, varied with the molecular weight M and, furthermore, that h approached a value of 2·0 Å as the value of M approached zero. For an α-helix $h_{M\to 0}$ should be about 1·5 Å. More recently, Parry and Elliott[3] have repeated some of the X-ray diffraction experiments of Luzzati *et al.*, using *m*-cresol as solvent, and suggest that the conclusions reached by the latter are erroneous, not because of faulty measurements but rather because of incorrect assumptions regarding the packing of the molecule. Parry and Elliott demonstrated that the α-helix is the probable conformation of the molecule of the PBLG sample investigated.

Prior to the study of PBLG in dichlorethane by light scattering when the solution was subjected to electric fields[4], we made conventional light scattering measurements. We evaluated our data after the method of Zimm[5], and in order to obtain information about the polydispersity of the sample we followed the treatment devised by Reichmann[6]. Using this method, a value for the weight-average length L_w is obtained from the slope of the high-angle asymptote of a graph of Kc/R_θ^1 against $\sin\theta/2$. The factor K is the usual constant prevalent in light scattering theory, c is the concentration, θ the angle between the forward direction of the incident beam and the scattered beam, and R_θ^1 is the Rayleigh ratio corrected by the term $\sin\theta/(1+\cos^2\theta)$. The following results were obtained: weight average molecular weight $2{\cdot}5 \times 10^5$, weight average degree of polymerization, $\overline{N}_w$, $= 1{\cdot}14 \times 10^3$, $\overline{L}_w = 980 \pm 50$ Å, $\overline{L}_z = 1550 \pm 80$ Å, $h = 1{\cdot}3$ Å and $h^1 = 0{\cdot}86$ Å. Here $\overline{L}_z$ is the $[Z(Z+1)]^{\frac{1}{2}}$ average length obtained from the Zimm plot data alone and $h = \overline{L}_z/\overline{N}_w$, whereas $h^1 = \overline{L}_w/\overline{N}_w$.

In their appraisal of the light scattering data taken from the literature, Luzzati *et al.* have given a curve of h against M (Fig. 6 of ref. 1) and have not considered polydispersity to be important. Our value of h fits their curve very well but the seemingly more correct value of h^1 falls considerably below the curve and indicates that if polydispersity were taken into account it would lead to a value of $h_{M\to 0}$ more nearly equal to 1·5 Å than to 2·0 Å. We suggest that the effect of polydispersity is much more important than Luzzati *et al.* have assumed. Our suggestion is further supported by the work of Spach *et al.*[2], from which, by reference to Fig. 4 of their paper, a value for $h_{M\to 0}$ of 1·5 Å is indicated.

We conclude, therefore, that if due attention is given to, and allowance made for, the polydispersity of the samples studied, then both the hydrodynamic and light scattering data will give a value of $h_{M\to 0}$ for the glutamate molecule indicative of the α-helix rather than the $3{\cdot}0_{10}$ helix.

A Means of Increasing the Oxidation Resistance of Diamond

IN the search for techniques by which to determine small amounts (0·01–1 per cent) of light-atom impurities in laboratory-prepared diamond[1], we have attempted to use strongly oxidizing melts and combustion in oxygen to destroy the host. Useful results for the carbon-13 distribution in undoped diamonds[2] have already been obtained by the direct combustion technique. However, straightforward combustion in oxygen did not produce complete oxidation of boron-doped diamonds. Microscopic examination of the incompletely burned diamonds and their behaviour toward alkali suggested that the residue was covered with a layer of boric oxide, which, being continuous and of low vapour pressure, inhibited further attack of oxygen on the diamond. Complete oxidation of the sample could be achieved only by alternately heating the sample at 800° C in oxygen and washing the residue in the platinum boat with successive portions of 1 N sodium hydroxide and water. The boric oxide that was removed from the diamond surface by these washing steps was determined by potentiometric alkalimetric titration of the borate in the combined wash solutions.

The oxidative stability of boron-doped diamonds, as disclosed by our attempts to analyse them, is illustrated by the following comparison with the oxidative stability of undoped man-made diamonds (RVG grade, commercially available from Metallurgical Products Department, General Electric Co., Detroit, Michigan) and with natural diamonds (from South West Africa). The boron-doped diamonds were prepared according to the class of conditions outlined in previous papers[1,3].

(1) Complete oxidation (800° C, pure oxygen) of all samples of undoped man-made diamonds and of natural diamonds was achieved within 24 h; in most cases oxidation was complete after 1 h.

(2) With one boron-doped sample a residue equal to 60 per cent of the initial sample weight still remained after an 8-h period of combustion; with another sample, 38·5 per cent of the initial sample weight remained after a 24-h period of combustion. The rate of weight loss was about 1/70 that of the RVG and less than 1/100 that of the natural diamonds.

(3) The residues from the boron-doped diamonds suffered no further weight change during a second 4-h period of combustion.

(4) Further oxidation of the residues from the boron-doped diamonds was achieved only after they had been washed with alkali.

(5) A marked increase in the oxidative stability of the RVG diamonds was observed when they were mixed with some powdered boron before combustion.

In addition to their potential technological importance, these results have an important scientific implication. The thermal oxidative etching of diamond is an investigatory technique used in the study of the origin of natural diamond, and inferences have been drawn from the results concerning the microstructural characteristics and thermal history of the diamonds. However, as the work reported here shows, small amounts of impurity can markedly change the oxidative behaviour of diamonds.

We thank K. A. Darrow for supplying quantities of boron-doped diamond and H. W. Middleton and Miss Nancy Parker for experimental assistance.

BIOCHEMISTRY

Glyoxylate Reductase Activity of Lactate Dehydrogenase

LACTATE dehydrogenase (L-lactate: NAD oxidoreductase, *EC* 1.1.1.27) occurs in most animal tissues in five different forms[1,2], which can easily be separated by electrophoresis, and these dehydrogenases are enzymes of substrate specificity. Meister[3], however, has found that a series of α,γ-diketo acids are reduced at an essentially uniform rate which is about one-tenth that for pyruvate. Markert and Møller[1] observed that a series of α-hydroxy acids are oxidized at different rates by the isozymes of bovine heart extract, and Kun[4] has shown that β-mercaptopyruvate is reduced by crystalline heart lactate dehydrogenase. It has been shown (unpublished) that β-hydroxybutyrate is a slowly reacting substrate. The present report presents evidence for the glyoxylate reductase activity (*EC* 1.1.1.26) of lactate dehydrogenase based on quantitative and qualitative studies of purified enzyme (Boehringer rabbit muscle lactate dehydrogenase) or rat liver extract. Quantitative determination of dehydrogenase activities was carried out by measurement of the diminution or production of reduced nicotinamide dinucleotide ($NADH_2$) (at 23° C and at a wave-length of 340 mμ).

A qualitative study of cellulose acetate electrophoresis[5] was performed at 4° C, and the enzyme activity was observed by staining the $NADH_2$ produced by the enzyme reaction with phenazine methosulphate and nitro-blue tetrazolium. The results are shown in Table 1 and Fig. 1.

Table 1. ACTIVITY OF THE PURIFIED LACTATE DEHYDROGENASE WITH TWO SUBSTRATES

(Specific activities are expressed as μmoles of $NADH_2$ reduced or produced/100 μg of protein/h)

Substrate		Specific activity
Pyruvate	0·0125 M	111·6
Glyoxylate	0·0125 M	105·6
Lactate	0·0125 M	1·2
Glycolate	0·0125 M	0·96

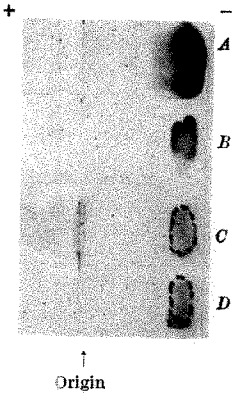

Fig. 1. Results of cellulose acetate, electrophoresis. *A*, Purified Boehringer rabbit muscle lactate dehydrogenase; *B*, rat liver extract; *C*, purified Boehringer rabbit muscle lactate dehydrogenase; *D*, rat liver extract. *A* and *B* developed with lactate; *C* and *D* developed with glycolate

Our results show that the lactate dehydrogenase catalyses glyoxylate reductase.

Except for the intensity of the bands, the patterns obtained on the cellulose acetate preparations, from the two different substrates, were identical. When glycolate was used instead, the pattern was much fainter. In view of the similarity in structure between the molecules of pyruvate and glyoxylate, and lactate and glycolate, the finding that these substrates are metabolized by the same system is not surprising.

Kun[6] has indicated that glycolate is oxidized to glyoxylate by a soluble liver enzyme, but its exact properties have not yet been established. It is well known that some single enzymatic proteins are capable of catalysing reactions with more than one substrate. These results would seem to provide further evidence for this concept, but more extensive investigations will be required to rule out the possibility of enzymatic contamination.

Peroxidation of Lipid from Normal and Paroxysmal Nocturnal Haemoglobinuria Erythrocytes

PREVIOUS investigations in this laboratory demonstrated that *in vivo* red cell damage in animals and humans during exposure to oxygen under high pressure was associated with peroxidation of erythrocyte unsaturated fatty acids[1,2].

In paroxysmal nocturnal haemoglobinuria (PNH), a rare disease characterized by intravascular haemolysis accentuated during sleep, the primary defect is in the stroma of the erythrocyte. The underlying mechanism of red cell destruction has not been clarified in spite of intensive investigation. Since some investigators reported that PNH erythrocytes contained increased quantities of unsaturated fatty acid, we examined the possibility that the lipid of PNH erythrocytes would form more lipid peroxides than that of normal erythrocytes under conditions known to cause lipid peroxidation.

Erythrocytes were obtained from three patients with documented PNH and compared to those of six normal control subjects. Lipid extractions were performed simultaneously on PNH and normal erythrocytes in each investigation and exposed simultaneously to ultra-violet radiation (known to cause lipid peroxidation)[3]. Lipids were extracted from 4 ml. of washed packed erythrocytes by a modification of the chloroform–methanol method described by Bligh and Dyer[4]. The final chloroform layer was evaporated to dryness under vacuum at 37° C and the lipid evaporate resuspended in 16 ml. of physiological saline and used immediately or frozen under nitrogen for storage.

Portions of extract were placed in 200-ml. quartz Erlenmeyer flasks and shaken at 100 c/m, 40 cm below an ultra-violet source (Westinghouse Sterilamp *G*15 *T*8). Lipid peroxides were determined before and after varying times of ultra-violet exposure (30 min, 1 h, 2 h, 3 h and 4 h) by the reaction of 2-thiobarbituric acid with malonylaldehyde. This reaction measures the products of lipid peroxidation rather than lipid peroxides themselves, and is generally accepted as a measure of lipid peroxidation[5]. A standard curve was prepared using 1,1,3,3-tetraethoxypropane which hydrolyses to yield malonylaldehyde[6]. Values for lipid peroxides were thus expressed as moles of malonylaldehyde.

Table 1. LIPID PEROXIDE FORMATION IN ERYTHROCYTE LIPID AFTER 30 MIN EXPOSURE TO ULTRA-VIOLET RADIATION

	Lipid peroxides mμmoles malonylaldehyde per ml. lipid extract
Normal subject	9
PNH No. 1	20

Values are the average of duplicate determinations in a representative experiment.

Table 2. LIPID PEROXIDE FORMATION IN ERYTHROCYTE LIPID AFTER 1 H EXPOSURE TO ULTRA-VIOLET RADIATION

	Lipid peroxides mμmoles malonylaldehyde per ml. lipid extract
Normal subjects	8–12
PNH No. 1	25
PNH No. 2	18
PNH No. 3	23

Values are the average of duplicate determinations in a representative experiment. The range of normal mean values is given.

Lipid from PNH erythrocytes consistently formed more lipid peroxides than that of normal erythrocytes (Tables 1 and 2). This difference was even apparent after only 7·5 min of ultra-violet exposure. Quantities of lipid peroxides determined by the 2-thiobarbituric acid reaction paralleled peroxide activity measured iodometrically.

There is general agreement that the basic lesion in PNH is intracorpuscular rather than extracorpuscular. Although Munn and Crosby in 1957 reported elevated unsaturated fatty acids in PNH red cells[7], other investigations failed to confirm these findings[8]. In the investigations described herein lipid extracts of PNH erythrocytes exposed to ultra-violet radiation yielded consistently higher lipid peroxide levels than the lipid extract of normal red cells. Since peroxidation involves unsaturated fatty acids, the increased lipid peroxide levels in PNH lipid extract most likely reflect elevated levels of stromal unsaturated fatty acid in PNH erythrocytes.

Recent work in this laboratory has shown that PNH erythrocytes were more susceptible to lysis by agents capable of peroxidizing lipid than normal erythrocytes. It is therefore possible that peroxidation of erythrocyte lipid may bear some relationship to the haemolytic mechanism in PNH. Cell damage could occur as a direct result of membrane damage by rupture of fatty acid double bonds, or as a result of the known toxic effects of lipid peroxides on protein and enzymes[9].

Search for a Naturally Occurring Amylase Inhibitor in Human Serum

IT has been postulated that an amylase inhibitor exists in normal human serum, but not in the serum of patients with acute pancreatitis[1]. The principal evidence for the presence of this inhibitor was based on observations that the average amylase activity of a group of sera was nearly tripled after subjecting the specimens to filter paper electrophoresis. It was found that when eighteen normal sera having a mean amylase value of 106 Somogyi units were separated electrophoretically, the total amylase recovered by extracting the various protein fractions with saline averaged 311 Somogyi units[1]. However, a similar electrophoretically-induced enhancement in amylase activity could not be demonstrated in sera from patients with acute pancreatitis. Dreiling *et al.*[2] substantiated these observations and suggested that although increased quantities of pancreatic amylase enter the blood in acute pancreatitis, the circulating level of the amylase inhibitor is decreased in this disorder. These workers further concluded that, in cases of pancreatic cancer, hyperamylasaemia was not accompanied by any diminution in the enzyme inhibitor.

Proof of the existence of an inhibitor of amylase has been derived exclusively from iodometric measurements of amyloclastic activity. Several independent investigations have recently indicated that certain protein components of serum are capable of interfering with the formation of starch-iodine colour and thereby altering amylase measurements based on this chromogenic response[3–5]. The dinitrosalicylic acid colour reaction introduced in 1921 by Sumner[6] for measuring reducing sugars is not adversely affected by serum proteins[7] and has been found applicable for the determination of amylase in serum[8]. It seemed desirable, therefore, to verify the existence of the postulated amylase inhibitor, by using the dinitrosalicylic acid method to investigate the distribution of amylase activity in normal and abnormal sera before and after paper electrophoresis.

Aliquots of 0·85 ml. of serum were applied to large (28·5 × 35 cm, Whatman 3*MM*) filter paper rectangles moistened with veronal buffer (*p*H 8·6, ionic strength 0·075). Electrophoresis was performed in a horizontal cell at a constant potential 80 V for 16 h. Following the separation, a 1·5-cm strip was cut longitudinally from the filter paper and stained for protein. The remainder of the rectangle was cut into 0·5-cm segments that were individually extracted with 0·85 per cent sodium chloride solution. The amylase activity in the saline eluates was

measured by the modified dinitrosalicylic acid procedure[8] and protein content was estimated at 280 mμ in a Beckman '*DU*' spectrophotometer[9].

The electrophoretic distribution of amylase was examined according to the described procedure in the sera of normal rabbits[10], normal and pancreatectomized dogs[11], healthy individuals and patients with various disorders[12]. Amylase recoveries from the electrophoretic strips ranged between 75–110 per cent of the total amylase of unfractionated serum, except in specimens from patients with acute pancreatitis. Amylase recoveries in the latter cases were always much lower than those obtained with normal human serum. In no instance did subjection to electrophoresis greatly increase amylase activity in any of the normal or abnormal specimens investigated.

In an attempt to demonstrate an amylase inhibitor, aliquots of pooled normal human serum were subjected to electrophoresis in duplicate. The segments from one strip were eluted with saline, whereas those of the other strip were treated with a mixture of saline and serum (250:1). After correction for the amylase activity of the serum in the saline–serum mixture, the electrophoretic distributions of saccharogenic activity were quite similar in both types of eluates (Fig. 1). The recovery of serum amylase activity in both cases was approximately 80 per cent. Of special interest is the fact that the presence of normal human serum in the saline eluting fluid did not depress amylase activity as might have been expected if the extractant mixture had contained an inhibitor.

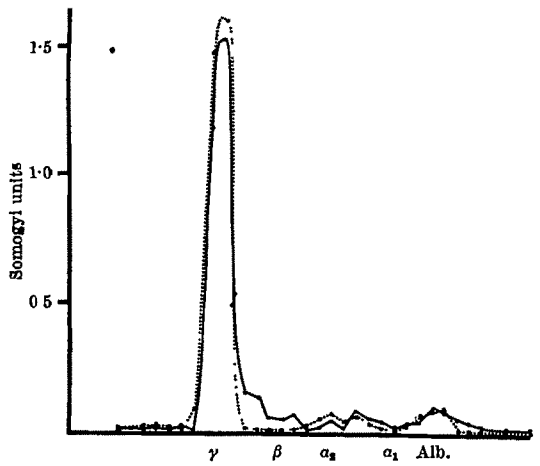

Fig. 1. Electrophoretic distribution of saccharogenic activity on strips prepared from pooled normal human serum and extracted with saline (——) or a saline–serum mixture (- - - -)

The major part of the saccharogenic activity in normal human serum and in the sera of patients with various clinical disorders is consistently found in the gamma-globulin zone[8]. Only trace amounts of activity of questionable significance are isolated from the other electrophoretic areas. These observations are in sharp contrast to the patterns obtained when an amyloclastic method is used to determine amylase activity. With an iodometric procedure, amylase activity is evident in both the albumin and gamma-globulin regions, but particularly in the former.

Exposure of electrophoretic eluates to boiling water for 30 min completely abolishes amyloclastic activity in the gamma-globulin zone[13]. Such treatment, however, enhances the amylase activity in the albumin-area extracts. It is unlikely that this increase in apparent amyloclastic activity in the heated albumin-containing eluates is enzymatic in nature, since incubation in boiling water would be expected to destroy most enzymes. Protein, particularly serum albumin, has been shown to interfere with the starch-iodine reaction[14]. The strikingly increased recoveries of amylase in the albumin zone of heated serum eluates as determined by the iodometric method could therefore be accounted for by protein interference with the starch-iodine colour reaction.

The low saccharogenic recovery of amylase after electrophoresis of serum from acute pancreatitis patients is worthy of special note. The magnitude of the amylase activity isolated from the electropherograms prepared from these sera was found to be dependent on the time of exposure to the electric current. For example, lesser amounts of saccharogenic activity were recovered from the gamma-globulin zone following 16 h of electrophoresis as compared to an 8-h separation. It is possible that heat generated during electrophoresis may be a factor contributing to the loss of enzymatic activity. It is interesting to note the nearly complete recoveries of amylase obtained following fractionation of serum from acute pancreatitis patients by gel filtration. Heat is not evolved during this chromatographic procedure.

In order to investigate the sensitivity of the enzyme to heat, amylase activity was measured saccharogenically in serum pooled from normal subjects and serum pooled from patients with acute pancreatitis. After the samples of each pool had been incubated at 45° C for 16 h, the amylase determinations were then repeated (Fig. 2). This storage temperature had little effect on the saccharogenic activity of the normal pool. However, exposure of the abnormal specimen to 45° C caused a marked reduction in amylase activity. This behaviour suggests a possible physicochemical difference between amylase which circulates normally and that present in the serum of patients with acute pancreatitis.

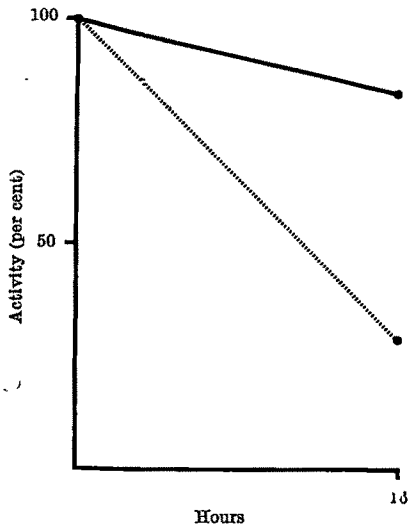

Fig. 2. Effect of a 16-h incubation at 45° C on the saccharogenic activity of pooled normal human serum (——) and serum pooled from patients with acute pancreatitis (- - - -)

The apparent increase in normal serum amylase activity measured iodometrically following electrophoresis is probably due to protein interference with the starch-iodine colour reaction rather than inactivation of a hypothetical amylase inhibitor. Use of a saccharogenic method to measure amylase failed to provide evidence suggesting that normal human serum contains an electrophoretic-labile inhibitor of this enzyme. Reduced electrophoretic recoveries of amylase in specimens from acute pancreatitis patients may result from the presence of a molecular form of amylase that is highly susceptible to heat. This heat-labile amylase fraction may be derived from the inflamed pancreas and could conceivably be an isoenzyme.

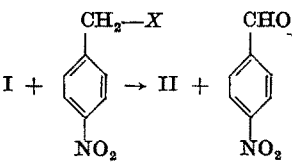
Reductive Conversion of Thiochrome to Thiamine



ALTHOUGH the chemistry of thiochrome was thoroughly developed during the period of thiamine exploration in the 'thirties[1,2], the biochemical aspects of this pigment were neglected, mainly because of the early reports on its apparent inactivity in the carboxylase reactions[3]. Recent investigations by Titaev[4], however, have suggested a major role for thiochrome; these reports have alleged that an enzyme, thiamine dehydrogenase, catalyses the oxidation of thiamine to thiochrome with the subsequent reduction of oxidized adrenaline. The existence of this enzyme system, however, has been both refuted[5] and affirmed[6] in recent years, and at the present time it is difficult to assess the biological significance of the reaction.

The mechanism of the model thiamine-catalysed reactions has been of interest to us for several years and recently we have investigated the chemistry of both thiochrome and dihydrothiochrome in connexion with these reactions[7]. The oxidative conversion of the vitamin to thiochrome, to our surprise, was found to be rapid and occurred under mild conditions. When one suspends the vitamin in methyl alcohol and then adds three equivalents of potassium carbonate it is found that a brilliant blue fluorescence is produced after a few minutes. Analysis of the alcoholic solution by paper chromatography indicates that thiochrome is the fluorescent derivative. Under these conditions, the oxidation is incomplete; however, the oxidized products are thiochrome and thiamine disulphide. This result has led us to investigate a variety of oxidizing agents, and at the present time we have found that potassium permanganate, manganese dioxide, nitrobenzene, nitrosobenzene, iodine, cupric acetate, alloxan, ninhydrin, amyl nitrite and quinone are effective in this conversion (thiochrome, 4 per cent; thiamine disulphide, 85–90 per cent isolated). The conditions for the reactions are as follows. The appropriate oxidizing agent (10^{-3} moles) was dissolved in absolute methanol (50 c.c.) and the mixture was stirred to facilitate solution (additional alcohol was added if solution was not complete). Thiamine (10^{-3} moles) was then suspended in the alcohol. After stirring for a few minutes, sodium methoxide or potassium carbonate (3×10^{-3} moles) was added and this reaction mixture was stirred for 1 h. At the end of this time, the reaction was neutralized with glacial acetic acid and filtered. The concentration of thiochrome was determined by measuring an aliquot of this solution at 375 mμ on the Beckmann '*DB*' Spectrophotometer. The remaining solution was evaporated to dryness on a rotary evaporator and the residue was then suspended in a water–acetone mixture overnight. Recrystallization of the semi-solid from acetone gave thiamine disulphide (85–90 per cent).

This rapid non-enzymatic conversion is the basis for the dispute over the existence of thiamine dehydrogenase, since it is difficult to ascertain whether or not the enzymatic oxidation is significant. Since the oxidation is disputed and the reduction of thiochrome has not been investigated, it was concluded that a reduction study might afford information on the ease of such a conversion, if not direct evidence for the enzymatic reaction. If one were to make an *a priori* judgment on the biochemical mechanism of such a conversion, it would be concluded that three reaction pathways would be favoured: (1) a reductive decarboxylation; (2) a reductive isomerization; (3) a direct reduction. Conditions for (1) and (2) have already been described[8,9]. When thiochrome is reacted with α-chloropropionic acid in the presence of alkali, thiochrome (I) is converted to dihydrothiochrome (II):

Similarly, the reductive isomerization was also accomplished by reacting thiochrome with *p*-nitrobenzyl halides under alkaline conditions. This reaction gives dihydrothiochrome, and *p*-nitrobenzaldehyde:

Although these reactions are of interest to the model thiamine-catalysed reactions it is unlikely that they are of significance to the biochemical reactions. Instead, it would be expected that the third mechanism, a direct reduction with DPNH or other suitable reducing agent, would be the most likely reaction pathway. In order to investigate this pathway, an investigation was undertaken of both model and enzymatic reductions of thiochrome.

It was concluded that the simplest experimental approach to this problem would be to assay for carbon

dioxide produced from the thiamine-catalysed decarboxylation of pyruvic acid. Since thiamine is relatively unstable under the alkaline conditions of the model reactions, a standard (corresponding to 100 per cent reduction of thiochrome) was compared with the various runs containing thiochrome and the appropriate reducing agent. The results of this experiment are summarized in Table 1.

Table 1. MODEL THIOCHROME REDUCTIONS

Reducing agent	μl. Carbon dioxide/h
(1) Standard	34
(2) Benzaldehyde	20
(3) DPNH	6
(4) Lactic acid	5
(5) Acetaldehyde	4
(6) Ascorbic acid	0

Standard double-arm Warburg flasks were used. In the side-arms were placed the appropriate reducing agent and concentrated sulphuric acid. Thiochrome (1×10^{-5}) and sodium phosphate buffer (0·2 moles, *p*H 8·3) were placed in the main compartment. The flasks were equilibrated under a nitrogen atmosphere at 30° C for 15 min. The reducing agent was then poured into the main compartment and the reaction was allowed to run for 1 h. At the end of this time, acid was added to stop the reaction, and final readings were taken after re-equilibrating for 15 min. Under these conditions, it was found that most of the reducing systems did not yield sufficient thiamine (at least not at a sufficient rate to overcome the base catalysed decomposition of the vitamin) to show significant reduction of thiochrome. The notable exception, however, was benzaldehyde which apparently reduced the pigment by way of a Cannizzaro reaction to give approximately 57 per cent thiamine. Based on the results of the model system, an attempt was also made to reduce thiochrome enzymatically. This investigation, however, was not successful because it was found that thiochrome inhibited the decarboxylation of pyruvic acid to a considerable extent. When the method developed by Schuster and Lohman was used[10] it was found that a reaction mixture containing benzaldehyde, thiochrome and yeast afforded 50 μl. of carbon dioxide; a similar mixture without thiochrome afforded 85 μl. Similar results were found with the other reducing agents.

In conclusion, it can be stated that the chemical conversion of thiamine to thiochrome occurs under mild conditions, and this reaction may be of biochemical significance. The transformation of thiochrome to the vitamin by biochemical agents does not, however, occur at a sufficient rate to allow a firm decision to be made on its possible physiological importance.

This investigation was supported by a U.S. Public Health Service research grant from the National Institute of Arthritis and Metabolic Diseases.

Serum ATP : Creatine Phosphotransferase Activity in Guinea-pigs with Experimental Muscular Dystrophy

HOSENFELD *et al.*[1] have recently reported investigations of plasma creatine kinase (ATP : creatine phosphotransferase) activity in mice with hereditary muscular dystrophy indicating that the disease in mice is more closely related to the limb girdle type of human muscular dystrophy than the Duchenne type of muscular dystrophy.

Experimental muscular dystrophy in guinea-pigs, induced by placing young guinea-pigs on a vitamin E-deficient diet, has also provided evidence of a similarity to human dystrophy when studying the tissues of guinea-pigs in the 'pre-clinical' and early clinical stages of the disease. Schottelius *et al.* have demonstrated altered mechanical properties[2], significant changes in myoglobin concentration[3–5], and oxygen consumption in the resting and stimulated muscle[6]. Bird and Szabo have recently correlated these changes with ubiquinone and tocopherol concentrations and lipid peroxidation of the tissues[7]. The object of the present investigation was to compare the serum ATP : creatine phosphotransferase activity in developing experimental muscular dystrophy of the guinea-pig with results reported for hereditary muscular dystrophy of the mouse and the human myopathies.

Thirty-day-old male English strain guinea-pigs, average weight 325 g, were maintained on one of the following dietary regimens: 'Purina Lab Chow' pellets (normal), synthetic vitamin E-deficient diet[2] or the synthetic diet supplemented with *dl*-α-tocopherol. The *dl*-α-tocopherol was suspended in olive oil (15 mg/0·5 c.c.) and 0·5 c.c. administered orally every third day. Food was withheld 4 h prior to supplementation and replaced 4 h after supplementation. On days of tocopherol supplementation, animals on normal and vitamin E-deficient regimens received 0·5 ml. of olive oil without tocopherol. All animals received 0·5 ml. of cod liver oil and 25 mg of sodium ascorbate on days tocopherol supplement was not given. Fresh diet was prepared twice a week.

Blood was drawn by heart puncture following light ether anaesthesia and allowed to clot at room temperature for 1–2 h. The clotted blood was centrifuged at 2,500 r.p.m. for 15 min; the serum was separated and again centrifuged for an additional 15 min to remove any remaining cells. Duplicate determinations were made 2 h after killing the animals.

ATP : creatine phosphotransferase activity was determined by the method of Tanzer and Gilvarg[8] in which the ADP, formed in time with creatine as substrate, is phosphorylated by phosphoenolpyruvate in an auxiliary reaction catalysed by pyruvate kinase: the pyruvate formed is determined with the indicator reaction catalysed by lactic dehydrogenase; the rate of oxidation of DPNH is a measure of the ATP : creatine phosphotransferase activity. Results of enzyme activity are expressed in International Units (I.U.).

Student's small sample '*t*' test was used for the statistical analysis with a probability of $P \leqslant 0{\cdot}01$ being accepted as revealing a significant difference.

Table 1 shows the mean serum enzyme activity of the guinea-pigs at feeding durations of 15, 21 and 30 days. The data indicate that the enzyme activity is not significantly different in the serum from the animals from the three dietary regimens at 15 days of diet. At 21 and 30 days of diet, serum from vitamin E-deficient animals is significantly greater in activity than either the normal or vitamin E-supplemented animals, with no significant difference between the normal and vitamin E-supplemented animals. It is also noted that there is no significant difference between the normal animals for the three feeding durations. Vitamin E-deficient enzyme activity is significantly greater in the 21-day animal serum than the 15-day vitamin E-deficient serum, and continues to be high in the 30-day animals.

A point of emphasis in this communication is the investigation of guinea-pigs in the beginning stages of experimental muscular dystrophy. Secondly, we have used a young herbivore in which the muscle fibres are still in the process of biochemical and structural maturation[9], and are more sensitive to the presence of highly unsaturated fatty acids such as are provided by supplementation of cod liver oil. Older animals acquire greater tissue concentrations of vitamin E through dietary sources[10], and relatively long periods of time are required to induce the manifestations of vitamin E-deficiency.

Table 1. GUINEA-PIG SERUM ATP: CREATININE PHOSPHOTRANSFERASE ACTIVITY

(I.U. units)

Diet	Feeding duration 15 Days	21 Days	30 Days
Normal	(6) 1·44 ± 0·30*	(12) 1·76 ± 0·32	(13) 1·94 ± 0 28
Vitamin E-suppl.	(8) 1·17 ± 0·36	(6) 1 40 ± 0·39	(8) 2·91 ± 0·33
Vitamin E-defic.	(9) 2·95 ± 0·62	(8) 7·49 ± 1·12†	(6) 4·76 ± 0 38†

* Mean ± standard error; parentheses indicate number of animals studied in each group.
† Significantly different from normal and vitamin E-supplemented animals ($P \leq 0$ 01).

Growth of the guinea-pigs on the synthetic diet was not optimal even when supplemented with reasonably large amounts of vitamin E. For the first 5 days, animals fed the synthetic diet supplemented with vitamin E had a slower growth-rate than those animals fed the 'Purina Lab Chow' diet, but thereafter had the same growth-rate for the duration of the experiment[7]. The increase in enzyme activity of the vitamin E-supplemented animals at 30 days of diet is a further indication of the sub-optimal conditions of the synthetic diet.

Previous investigations in our laboratory and others, using guinea-pigs and the same dietary regimen, have shown metabolic evidence of dystrophy at 15 days of diet. We have termed this stage as 'pre-clinical', in that there was no creatinuria, significant histopathological lesions, or typical external gross symptoms. Serum ATP : creatine phosphotransferase activity, which is considered as a clinical diagnostic test, was shown in this study to be not significantly different in the three groups of animals at 15 days. Since serum ATP : creatine phosphotransferase is of muscular origin[11], and increases in serum activity are more likely a function of membrane alteration[12], it appears that the permeability of the muscle cell membranes to this enzyme has not been altered in this early stage of vitamin E-deficiency. Several investigators[13–15] have postulated that vitamin E exerts its effect by neutralizing free radicals which arise in the initial stages of an antioxidative chain-reaction, and lack of the vitamin results in peroxidation damage to cellular structures. Previous investigations in our laboratory have shown no significant change in muscle lipid peroxidation, even though there was a significant decrease in α-tocopherol concentration at 15 days of vitamin E-deficiency[7].

After 21 days of vitamin E-deficient diet, the animals have creatinuria, typical histological changes in the muscles, significant decreases in muscle myoglobin[3–5], and oxygen consumption[6], and significant increases in lipid peroxidation[7]. The significant increase in serum ATP : creatine phosphotransferase at this time would conform with the idea that the serum enzyme is of muscular origin, and is released into the blood when metabolic events are such as to alter the permeability of the muscle membrane. The initial biochemical lesion remains to be demonstrated.

Comparing our results with those of others working with different species we find: the mean serum enzyme activity of normal and vitamin E-supplemented animals to be in the same range as healthy humans[12], and much lower than the activity reported for normal Swiss albino mice and heterozygote litter mates of dystrophic mice[1]. The evidence indicates that the enzyme activity increases in the initial stages of vitamin E deficiency, and then has a tendency to decrease as the disease progresses ($P = 0{\cdot}08$). We hesitate to conclude that these conditions have an identity with human types of dystrophy since it is likely that a variety of metabolic and membrane defects in muscle cells can alter the escape of the soluble muscle proteins, including enzymes[16].

Response to Vitamin D in Adrenalectomized Animals

IN recent years there have been repeated attempts to establish that the action of vitamin D is in some way mediated through the adrenal glands. Perhaps the first such suggestion came from Raoul and Gounelle[1], who described an increase in an ultra-violet absorbing material in the adrenal glands of rats given vitamin D. The same authors also reported that the adrenals accumulate a large fraction of the administered vitamin shortly after supplementation. Neither Kodicek *et al.*[2], Blumberg *et al.*[3] nor Norman and DeLuca[4], using either ^{14}C- or tritium-labelled vitamin D, were able to confirm the latter observation. In fact, in this laboratory no more than 0·3 per cent of the labelled vitamin administered has ever been found in the adrenals.

Recently, Quarterman[5] has been able to repeat Raoul's experiments demonstrating an increase in a 262, 275 mμ absorbing material in the adrenals of rats following vitamin D administration, again raising the question of the participation of the adrenal glands in vitamin D action. Additional evidence for this idea has been produced by the experiments of Sallis and Holdsworth[6] in which an inhibitor of adrenal function, *o-p'*-D,D,D[1-(2-chlorophenyl)-1-(4-chlorophenyl)-2,2-dichloroethane], appeared to block the vitamin D stimulation of calcium absorption. These experiments therefore made it desirable that the question should be examined by a direct approach: can adrenalectomized rats respond to vitamin D?

Weanling male albino rats (Holtzman Co., Madison, Wisconsin) were fed a purified diet containing adequate calcium and phosphate for at least 3 weeks as described previously[7]. At the end of this period severe vitamin D deficiency was evidenced by a low serum calcium concentration (Table 1) and by reduced growth[8]. At this time one group of animals was adrenalectomized and sham operations were carried out on the second group. Adrenalectomized rats were given a 1 per cent sodium chloride solution in place of their usual water supply. All animals were allowed to recover for 5–7 days before vitamin D

treatment. At this time half the rats from each group were given 2,000 I.U. of vitamin D_3 orally in 0·1 ml. of cottonseed oil, while the remainder received the same amount of cottonseed oil without the vitamin. All animals were killed 15 h later by decapitation, their blood was collected and everted intestinal sacs were prepared as described previously[9]. The sacs were filled with Krebs–Ringer bicarbonate containing 10^{-4} M $^{40}Ca - ^{45}Ca$ and 0·01 M glucose. They were incubated in the same solution at 37° C under an atmosphere of 95 per cent oxygen, 5 per cent carbon dioxide for 1·5 h. On completion of the incubations, portions were taken from the sacs and the incubation medium, plated as infinitely thin samples and the calcium-45 present was counted in a thin end window Geiger–Müller counter. The ratio of the calcium-45 concentration inside the sac to that in the incubation medium was taken as a measure of calcium transport against the concentration gradient[10]. The collected blood was allowed to clot and then centrifuged to collect the serum. Calcium of the serum was determined by the method of Webster[11].

The results (Table 1) clearly demonstrate that adrenalectomy does not prevent the well-established responses to vitamin D. In fact, the serum calcium-levels both in the presence and absence of vitamin D are not in any way affected by the presence or absence of the adrenal glands. However, it is of interest that the adrenalectomy did increase the ability of the gut sac from vitamin D deficient animals to transport calcium. This is in harmony with the observation of Harrison and Harrison[12] that the adrenal steroid cortisol inhibits calcium transport. Similar results were obtained by Sallis and Holdsworth[6], although they demonstrated that a single dose of cortisol stimulates calcium absorption while chronic treatment inhibits it. It would therefore appear that the adrenals themselves must influence calcium transport in the intestine quite apart from the action of vitamin D. Why adrenalectomy did not increase calcium transport in rats given vitamin D cannot be determined at the present time, although it is possible that a maximal rate of calcium transport has already been attained in these animals.

The present experiments cast doubt on the physiological significance of the data of Quarterman[5] and Raoul and Gounelle[1] with regard to the action of vitamin D. There seems little doubt that production of an ultra-violet absorbing material by the adrenals is stimulated by vitamin D administration. However, this material certainly does not appear to be involved in the physiological action of the vitamin, but may reflect an influence of vitamin D in adrenal metabolism.

We have also found that 90 mg of *o-p'*-D,D,D given to each rat failed to block the vitamin D induced rise in serum calcium. Either the *o-p'*-D,D,D does not function in the rat as in the chicken, or insufficient dosages were used. The fact that animals will respond to vitamin D in the absence of their adrenals may suggest that the *o-p'*-D,D,D inhibits the action of vitamin D directly. This can only be answered by a more detailed investigation. The present data are, however, sufficient to rule out the possibility that adrenal glands are required for the characteristic actions of vitamin D.

Table 1. FAILURE OF ADRENALECTOMY TO BLOCK VITAMIN D ACTION

	Serum calcium mg per cent	Intestinal ^{45}Ca transport 'ratio'*
Vitamin D deficient (sham operated)	5·1 ± 0·2†	2·09 ± 0·15†
Vitamin D deficient + adrenalectomy	5 1 ± 0 6	2·96 ± 0 51
Vitamin D deficient + vitamin D	7 7 ± 0·7	3·66 ± 0·44
Vitamin D deficient + adrenalectomy + vitamin D	7·9 ± 0·7	3·87 ± 0·53

Vitamin D deficient rats were either sham operated or adrenalectomized and 7 days later were either given 2,000 I U. of vitamin D_3 in 'Wesson' oil or 'Wesson' oil alone. They were killed 15 h later and their serum calcium and gut sac transport of calcium-45 determined.

* 'Ratio', calcium-45 serosol side: calcium-45 mucosal side.

† Standard deviation = $\sqrt{\frac{\Sigma d^2}{(n-1)}}$. There were at least nine rats in each group

Mechanism of Action of Bacterial Endotoxin

THE amount of endotoxin required to produce fatal traumatic shock by the intracerebral route is roughly one-twentieth of that required by the intravenous route[1]. The smaller dose is harmless when given intravenously. Shock following the injection of endotoxin into the brain is therefore the result of an action on the peripheral vessels from a distance—through the sympathetic nervous system. Since the site of the critical lesion produced by sympathetic nerve hyperactivity is in the splanchnic viscera, blockade of the coeliac plexus was used in an effort to prevent the critical lesion. In a previous communication we reported that coeliac blockade by ganglionectomy or by a long-lasting regional anaesthetic prevents death in dogs and rabbits from shock produced by endotoxin given intravenously or intracerebrally[1]. Some 65 per cent of dogs and rabbits survived a degree of shock that would have produced a mortality exceeding 85 per cent in animals without blockade. Therefore, while endotoxin appears to be capable of acting directly on certain tissues (for example, granulocytes, platelets), the lethal effects of endotoxin appear to be mediated by the catecholamines released in the splanchnic tissues.

We have recently confirmed this observation by the following means. A sublethal dose of endotoxin given intravenously to 24 rabbits was followed within one hour by a much smaller dose. The mortality was 100 per cent, although the mortality from the sum of both doses given as a single dose was zero.

This experiment was repeated in twenty-four additional rabbits, but the coeliac plexus was blocked by percutaneous one to two per cent xylocaine some 15–30 min before the second dose. Twenty-two rabbits (91 per cent) survived. The two rabbits that died were killed by a needle tear of the aorta.

Since the first dose of endotoxin makes the rabbit extremely hypersensitive to the second smaller dose[2], the vasoconstrictor damage done by the first dose is to the system involved in detoxification of the second dose—the reticulo-endothelial system (RES) in liver and spleen. The additional ischemia produced by the second dose results in fatal collapse of the peripheral circulation. By abolishing vasoconstrictor activity in the liver and spleen, coeliac blockade prevents damage from the second dose and allows the RES system to recover. We shall present data elsewhere to show that blockade prevents the loss of the detoxifying function of spleen and the

severe intracellular structural damage that is seen by electron microscopy.

The defenceless state of the animal the RES of which is damaged by a sublethal dose of endotoxin is transient—for if the second fractional dose is given 4 h rather than 1 h after the first, the mortality is very much less (less than 50 per cent), and still less (about 25 per cent) if the interval is 12 h (ref. 2). These data are a rough measure of the rapidity with which a severely damaged RES recovers normal function.

From these data we confirm the conclusion reached previously that (*a*) endotoxin kills by virtue of an effect in the splanchnic viscera that it cannot produce when the splanchnic nerves are blocked, and (*b*) the shock produced by endotoxin is the result of excessive catecholamine activity in the splanchnic circulation, and not a consequence of whatever effect endotoxin may be capable of inflicting elsewhere. Thus we conclude that death from endotoxin is caused by the loss of integrity of the blood vessels in the splanchnic area as a result of excessive and unrelenting activity of the catecholamines produced by the splanchnic sympathetic nerves.

Separation of Two Different Substrates for Plasma Kinin-forming Enzymes

THE formation and possible function of plasma kinins have attracted considerable interest during recent years. The kinins have been shown to be formed from a fraction within the α-2 globulins of the plasma by the action of several enzymes. Kinin-forming enzymes are present in several glandular secretions, such as saliva and sweat. Another type of enzyme, called plasma kallikrein, is present in an inactive form in plasma. The first two plasma kinins identified were bradykinin[1] and kallidin[2,3]. Recently a third, methionyl-lysyl-bradykinin, has been prepared from bovine plasma[4]. It is not known, however, whether the various kinins are formed from one and the same substrate or if they originate from different substrate fractions within the α-2 globulins of the plasma. Nor is it known whether the various enzymes attack one and the same substrate molecule, or if they act on different ones.

Margolis and Bishop[5] showed that the rapid kinin formation with plasma kallikrein involves only about one-third of the total plasma substrate (kininogen), whereas trypsin or glandular kallikreins release kinins from the whole of the substrate. Their experiments could not tell whether two different substrate entities or only different parts of the same substrate molecules were involved in these reactions.

During experiments on lymph, evidence was obtained on the existence of two separate plasma substrates for plasma kinin-forming enzymes[6,7]. It has now been possible to separate two substrates from plasma by gel filtration through a 'Sephadex *G*-200' column. The substrates can also be separated by using a DEAE-'Sephadex *A*-50' anion exchange column, and the two separation procedures can be combined.

Two sources of plasma kallikrein were used; either a pseudoglobulin preparation from human plasma[8] or freshly glass-activated human plasma[9]. The pseudoglobulin preparation, which had been dialysed for more than 48 h, did not develop any kinin on incubation with saliva or with trypsin, and was thus itself without any substrate for kinin-forming enzymes.

The sources of glandular kallikrein used were cell-free saliva[10] or 'Padutin' (Bayer, Leverkusen, Germany).

The plasma or plasma fraction to be tested for substrate content was incubated at 37° C with one of the previously mentioned sources of enzyme. Aliquots of the mixture were removed at intervals and tested for kinin activity on the isolated test organ, which was either the virgin rat uterus or the guinea-pig ileum preparation. Kinin activity developed was evaluated by comparison to the effect of known doses of synthetic bradykinin (Sandoz, Ltd., Basle).

The separation procedures were as follows: citrated plasma was prepared from blood (one volume of 3·1 per cent sodium citrate dihydrate solution to 9 volumes of blood) taken with silicone technique. 50 ml. of this plasma was applied to a column (diameter 2·5 cm, height 120 cm) of 'Sephadex *G*-200' equilibrated with a 0·1 M *tris*-HCl buffer, *p*H 8·0, containing 0·2 M sodium chloride. Elution was carried out with the same buffer, and the flow rate was 20 ml./h. Fractions of 5 ml. were collected using an 'LKB' fraction collector. Substrate 1 was found in some of the earliest fractions containing protein. Substrate 2 occurred in later fractions (Fig. 1). Substrate 1 could be shown to develop kinin rapidly on incubation with glandular as well as with plasma kallikrein (Fig. 2).

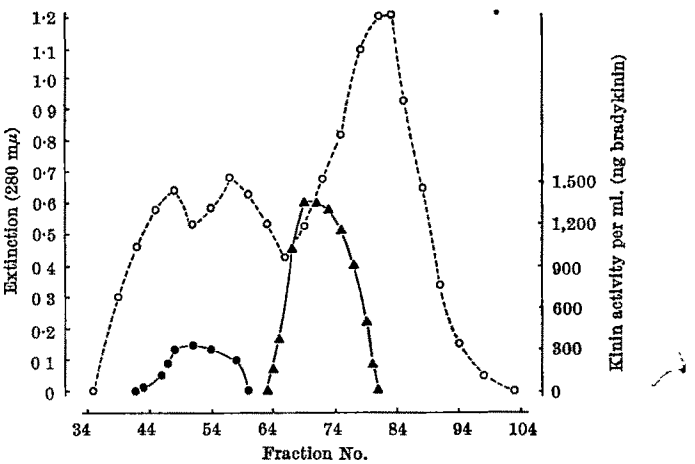

Fig. 1. Content of protein and of two substrates for kinin-forming enzymes in consecutive fractions (5 ml.) of human plasma from a 'Sephadex *G* 200' column (see text). O---- O, content of protein; ●——●, content of substrate 1; ▲——▲, content of substrate 2. Substrates are expressed in terms of kinin that could be developed per ml., synthetic bradykinin being used as reference. Protein content is expressed as extinction at 280 mμ, using a Zeiss spectrophotometer (Model '*PMQ* II') and a 1 : 16 dilution of the fractions

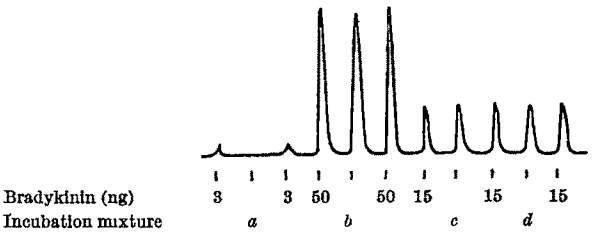

Fig. 2. Maximal kinin activity found in various incubation mixtures at 37° C. 0·1 ml. of the various mixtures added to the isolated rat uterus preparation in a 5 ml. organ bath (de Jalon solution, 29° C). Incubation mixtures: *a*, 0·2 ml. of a substrate 2-containing fraction and 0 1 ml pseudoglobulin preparation (plasma kallikrein); *b*, 0·2 ml. of a substrate 2-containing fraction and 0 1 ml. saliva; *c*, 0·2 ml. of a substrate 1-containing fraction and 0·1 ml. pseudoglobulin preparation; *d*, 0·2 ml. of a substrate 1-containing fraction and 0·1 ml. saliva. The fractions containing substrate 1 and 2 respectively were obtained by gel filtration through a 'Sephadex *G* 200' column. Standard doses of synthetic bradykinin added in between as indicated

Equal amounts of kinin activity could be obtained from this substrate with either of the two enzyme types. After maximal kinin formation by one of the enzymes, addition of the other enzyme did not cause any further kinin formation. The maximal activity from this substrate was obtained within 1 min on incubation with our plasma kallikrein preparations and within 4 min when saliva was used.

With substrate 2, only glandular kallikrein or trypsin caused a rapid kinin formation. With the plasma kallikrein preparation added to this substrate no kinin activity could be detected after 15 min of incubation (Fig. 2). On very prolonged incubation (36–48 h), however, substrate 2 could also be depleted by plasma kallikrein. Trypsin seemed to give somewhat more kinin activity with this substrate than did glandular kallikrein.

A DEAE-'Sephadex *A*-50' anion exchange column (diameter 1·1 cm, height 10 cm) equilibrated with 0·05 M *tris*-HCl buffer, *p*H 8·0, was also used for separation of the two substrates from citrated plasma or for further purification of the substrate fractions obtained by the gel filtration. Five ml. of plasma or 15–20 ml. of the fractions were first dialysed against 0·05 M *tris*-HCl buffer, *p*H 8·0, and then applied to the column. Elution of the column was carried out with the same buffer, its sodium chloride concentration being increased stepwise. Substrate 2 was eluted at a concentration of 0·2 M sodium chloride in the buffer, substrate 1 at a concentration of 0·3 M sodium chloride.

Fractions with substrate 1, which had been obtained by the gel filtration and by subsequent purification by the ion-exchange procedure, contained no plasma kallikrein and no kininase activity, whereas the fractions with substrate 2 contained a little kininase activity and some inactive plasma kallikrein. This plasma kallikrein could be removed by two successive exposures of the substrate 2 fractions from gel filtrations to large amounts of a silicate powder ('Speed plus', Great Lakes Carbon Corp., Los Angeles). The fractions were shaken with 100 mg of powder per ml. for 10 min at 37° C. After centrifugation at 2,200*g* for 5 min, the supernatant was again shaken with 50 mg silicate powder per ml. for 60 min at 37° C, followed by further centrifugation for 10 min at 2,200*g*. Finally, the fraction was filtered through a Whatman No. 1 paper before being applied to the ion exchange column.

The two substrates could be mixed with each other and re-separated again by gel filtration, each of them again occurring in the same fractions. No tendency towards transformation of one of the substrates to the other was seen on repeated gel filtration.

These findings of two separate substrates for kinin-forming enzymes may be of considerable physiological interest. It would be of importance to know which of the substrates is being utilized in the various tissues and situations where kinin formation is believed to play a part. It would also be interesting to know if the two substrates give rise to the same or to different kinins. Work is now in progress in our laboratory to obtain information on the type of kinins that are being formed from the two substrates with the various enzymes.

Formation of Esters from Acids by Brewer's Yeast: Formation from Unsaturated Acids

ESTERS are supposed to be of importance as flavour determinants in many products. A considerable number of esters have been detected in fruits[1–8] and in fermented beverages[9–11]. Jennings[4] has shown that the desirable pear aroma is largely due to volatile esters. Esters are also used in essences (primarily the esters with 6–8 carbon atoms in acid + alcohol)[1,7] and are generally accepted to be important contributors to the flavour and aroma of beer and wine. The threshold concentration for flavour perception is very low for some esters: it is 0·01 p.p.m. for ethyl isobutyrate for example, as has been reported by Harrison[12]. Sihto and Arkima[13] have reported that isopentyl acetate is deleterious to the flavour of beer at rather low concentrations.

Esters are formed as by-products of alcoholic fermentation[14]. The acid moiety must be activated to the corresponding acyl ~ SCo*A* derivative. In previous papers, I have reported that the amount of an ester formed depends on the supply of the corresponding alcohols[15] and acyl ~ SCo*A*-compounds[14,16,17]; these can be supplied by the metabolism of the yeast or via substances added to the medium[14]. For example, if valeric acid is added to the medium, considerable quantities of ethyl valerate are formed[16]. The correlation between ester formation and acid concentration can be expressed by means of a modification of the Briggs–Haldane equation for monomolecular enzyme reactions[18]. Some acids (propionate, isobutyrate and isovalerate) were not esterified at all[16]. At low concentrations of the acids a constant fraction was esterified. This fraction increased with increasing molecular weight of the acids; it was 2·6 per cent for butyrate and 12 per cent for caproate–caprylate[16].

The experimental approach of adding an acid (and in other experiments alcohols) to the medium increased the amounts formed considerably which facilitated the analyses. It also made the results independent of the formation of the acid during fermentation; the concentration of the acid was essentially constant during the experiment[16].

Unsaturated esters have been shown to be important to the flavour of fruits[5]. It was then thought to be of value to study the formation of esters from unsaturated esters.

A synthetic medium[19] (80 g/l. of glucose, 6·7 g/l. of Difco yeast nitrogen base and 36 mM of citrate, *p*H 5·3) containing different amounts of vinylacetic acid or hexen-3-oic acid was fermented with a strain of *Saccharomyces cerevisiae* (brewer's top yeast) at 20° C subjected to continuous stirring in flasks closed by means of one-way valves[19,20]. The media were analysed by means of gas chromatography for volatile esters[16] when the glucose was completely exhausted (as has been described elsewhere).

The results of the experiments are reported in Fig. 1. For comparison, experiments with butyric acid and caproic acid added to the medium are included[16]. Considerable amounts of ethyl esters were formed from vinylacetic acid and hexenoic acid; however, the curves for these two esters were significantly below the curves of the saturated isomers. The calculated value of the fraction esterified at low concentration of the acid has been tabulated in Table 1.

Table 1. KINETIC CONSTANTS OF ESTER FORMATION FROM SOME ACIDS IN FERMENTATION OF A SYNTHETIC MEDIUM WITH A STRAIN OF BREWER'S TOP YEAST

Calculated from Figs. 1 and 2

Acid	Michaelis constant (mM)	Maximum velocity (μM)	Esterified fraction at low conc. of the acid (μM)
Butyric	8	220	2·6
Vinylacetic	20	60	0·6
Caproic	1·4	130	12
Hexen-3-oic	5	70	2·5

Straight lines were obtained in double reciprocal graphs (Fig. 2) (Lineweaver–Burk plots). From the intercepts, the results of Table 1 were obtained. The Michaelis constants were higher and the maximum velocities were lower for the unsaturated acids than for the saturated acids (Table 1).

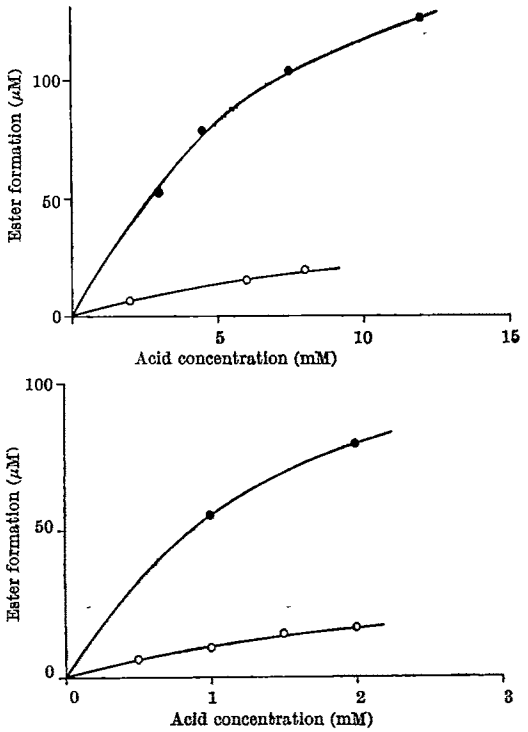

Fig. 1. Ester formation from some acids in fermentation of a synthetic medium with a strain of brewer's top yeast. Upper diagram, butyrate (●) and vinylacetate (○). Lower diagram, caproate (●) and hexen-3-oate (○)

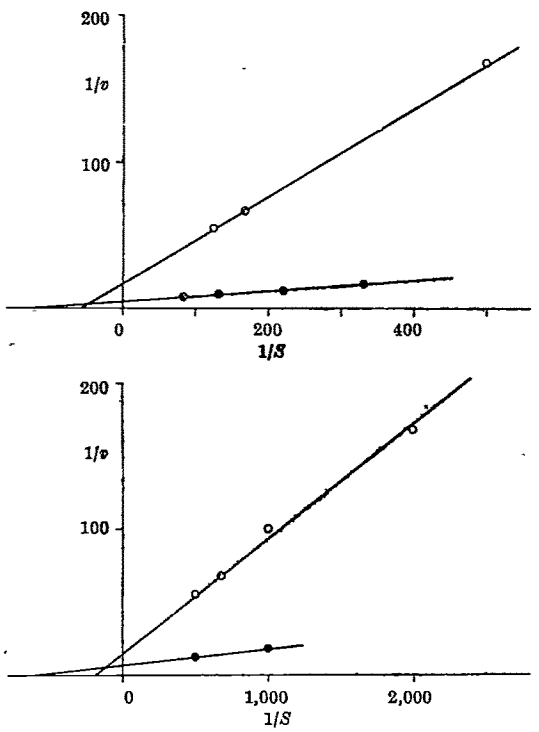

Fig. 2. Double reciprocal graph $1/v$ against $1/S$, where v is the formation of various ethyl esters (mM), and S the concentration of the corresponding acids (M). Upper diagram, ethyl butyrate (●) and ethyl vinylacetate (○). Lower diagram, ethyl caproate (●) and ethyl hexen-3-oate (○)

Thus, unsaturated acids were esterified, but to a lower extent than saturated acids. Whether this finding is of importance in brewing, for example, is uncertain since few quantitative results have been reported concerning the acids found in beer. Åyräpää *et al.*[21] have found about 1 p.p.m. of hexenoic acid in Swedish beers. About 0·03 p.p.m. of ethyl hexenoate is to be expected from the results of Table 1 and Fig. 1. This value is presumably of the same order of magnitude as the threshold value for flavour perception[12].

A Simple Medium for the Propagation and Maintenance of Human Diploid Cell Strains

THE experiences of many workers propagating human diploid cell strains (HDCS) suggest that these cells are uncommonly exacting in their medium requirements[1,4]. Eagle's basal medium (BME)[2] and minimum essential medium (MEM)[3] have given most satisfactory growth, but careful adherence to these formulae in preparing the media has not always guaranteed their suitability[4]. Differences in the purity of the constituents may account for the variability of different batches of media[4]. The use of standardized Eagle's media[4] has largely overcome these difficulties, but it is of interest to report that a simplified Eagle's medium has also been used successfully for the growth and maintenance of cells in our laboratory.

For the purpose of this study it was decided to investigate the amino-acid content of BME, and to determine whether the quantities used in Eagle's medium were critical for the propagation and maintenance of HDCS. It was also decided to investigate whether, in the absence of defined concentrations of the amino-acids used in BME, these amino-acids contained in the serum added to BME might be present in quantities adequate to support cell growth. Preliminary investigations were concerned with screening tests to preclude any unnecessary amino-acids. In subsequent studies only salts, vitamins and two amino-acids were incorporated in BME. The efficacy of experimental media was assessed by comparing results with those obtained using complete BME as a control medium.

BME contains thirteen amino-acids, nine vitamins, salts and glucose. Several modifications of this medium were made as follows: (i) Twelve combinations based on BME, but each deficient in one of the amino-acids. (ii)

A medium (S-BME) which was simplified BME containing only two of its amino-acids. In addition, galactose was substituted for glucose, and no sodium bicarbonate was present. The formula is as follows:

Salts and galactose (modified Hanks's balanced salt solution)	(g/l.)
NaCl	8·0
KCl	0·40
$MgSO_4 7H_2O$	0 20
Na_2HPO_4	0 05
$CaCl_2$	0·14
Kh_2PO_4	0·06
Galactose	2·0
Amino-acids (quantities as in BME)	**mM**
L-cystine	0 05
L-glutamine	2·0

Vitamins (Based on BME)	(mg/l.)
Biotin	1·0
Choline chloride	1·0
Folic acid	1·0
i-Inositol	0·2
Nicotinamide mononucleotide	1·0
Calcium pantothenate	1·0
Pyridoxal hydrochloride	1·0
Riboflavin	0·1
Thiamine hydrochloride	1·0
Phenol red	10·0

The *p*H of the medium was adjusted to 7·1–7·2 using N/10 sodium hydroxide.

(iii) Complete BME, but with the sodium bicarbonate concentration reduced to 0·1 per cent.

In all these media the vitamins and amino-acids were obtained from Nutritional Biochemical Corporation, Cleveland, U.S.A., and the salts from Hopkin and Williams, Ltd., Chadwell Heath, England.

For the maintenance of cells, no serum was added to these media but for serial propagation unheated calf serum was added to a final concentration of 10 per cent. None of the media contained antibiotics.

Cultures of two normal human foetal lung cells were used: (i) *WI*-38, developed at the Wistar Institute, Philadelphia, by Dr. L. Hayflick[5]; (ii) *MRC*-1, developed at the Medical Research Council Laboratories, Hampstead.

Quantitative analysis of serum for the thirteen amino-acids used in BME was carried out chromatographically, using the method of Stein and Moore[6]. The same batch of calf serum was used in all media.

Cells were propagated by the method described by Hayflick and Moorehead[7] using 4-oz. medical-flat bottles. For maintenance studies they were incubated in stationary 4-oz. bottles, but rolled when in test-tubes. Cultures used for maintenance studies did not have the medium replaced; all cultures were incubated in rubber-stoppered containers at a temperature of 36°–37° C. Cell counts were made in a haemocytometer on both unstained and trypan blue-treated cells.

Initial studies on the propagation of cells indicated that the omission of L-cystine and L-glutamine gave medium unsatisfactory for cell growth, whereas the exclusion of any of the other amino-acids did not seem to impair growth. Satisfactory results for cell propagation were obtained using S-BME with added serum, although cells maintained readily on this medium in the absence of serum. Substituting galactose for glucose reduced fluctuations in the *p*H of the medium during cell propagation.

The normal life span of these cells *in vitro* is 50 ± 10 passages. Cell senescence in this study began at the 44th to 47th passage as indicated in Table 1. Since the limited life of both cell strains is shown to be similar in both control and experimental media, it is clear that the use of S-BME has not altered the life span of the cells.

Table 1. PROPAGATION OF CELLS IN BME AND S-BME

Cell	Passage No.	Medium	No. of sub-cultures
WI-38	24–44	BME	22
WI-38	24–45	S-BME	23
MRC-1	26–47	BME	22
MRC-1	26–47	S-BME	22

Table 2. MAINTENANCE OF CELLS IN BME AND S-BME

Cell	Passage No. Bottles*	Tubes†	Medium	No. of days during which cells remained satisfactory‡ Bottles	Tubes
WI-38	24	21	BME	10	10
WI-38	24	21	S-BME	12	11
MRC-1	26	21	BME	9	12
MRC-1	26	23	S-BME	8	12

* Four bottles per medium.
† Ten tubes per medium.
‡ Earliest sign of cell degeneration.

Cell counts made on four occasions from confluent monolayers of cells after the same time interval for both control and experimental cultures showed that the rate of growth of cells in S-BME was slightly reduced, the average ratio of cells grown in experimental medium to those grown in control medium being 87 : 100.

Not only do the cells propagate satisfactorily in S-BME but the data in Table 2 show that they maintained equally well in both S-BME and BME.

The effect on the amino-acid content of adding serum to the medium is shown in Table 3, from which it is clear that in no case has the addition of serum resulted in a substantial increase in the concentration of any of the amino-acids; indeed, most are increased by no more than 20 per cent.

Table 3. CONCENTRATIONS OF AMINO-ACIDS IN BME AND IN CALF-SERUM SUPPLEMENT

Amino-acid	Concentration in BME (mM)	Concentration in serum (mM/100 ml.)*	Percentage of increase in amino-acid concentration after serum added†
L-Arginine	0·1	0 020	20
L-Cystine	0·05	0·023	46
L-Histidine	0 05	0·028	56
L-Isoleucine	0·2	0 012	6
L-Leucine	0·2	0·027	14
L-Lysine	0·2	0 051	26
L-Methionine	0·05	0 002	4
L-Phenylalanine	0·1	0·009	9
L-Threonine	0·2	0·017	9
L-Tryptophan	0·02	0·003	15
L-Tyrosine	0 1	0·006	6
L-Valine	0·2	0·039	20
L-Glutamine	2·0	0 022	1

* Final concentration of serum in growth medium is 10 per cent.
† Maximum value (common 'peak' for serine and glutamine).

These findings show that a defined medium of simple composition, with added serum, is suitable for the propagation of human diploid foetal lung cell strains. They also show that confluent sheets of non-replicating cells can survive in this medium in the absence of serum. Although the rate of growth of cells in the medium is slightly reduced compared with that in the more complex BME, this is not considered to be a practical disadvantage. By substituting galactose for glucose no difference in the rate of cell propagation occurs but it results in diminished glycolysis, so that the *p*H range is more uniform during cell growth.

The quantities of amino-acids provided by the added serum are insufficient, in themselves, to account for the satisfactory growth and survival of cells. It would seem that, on a quantitative basis, apart from cystine and glutamine the other eleven amino-acids used in BME need to be added in appreciably smaller quantities, or in some cases may not need to be added, to produce satisfactory propagation of cells, and that for the survival of cells these eleven amino-acids can be omitted. Optimal ranges or concentrations of amino-acids have not been determined, but smaller quantities of these components than present in BME are shown to be adequate.

Further investigations of a complementary nature on the vitamin requirement of the cells and an extension of these studies to a quantitative determination of the minimal and optimal nutritional requirements are contemplated.

I thank Dr. D. G. Smyth for determining the concentration of amino-acids in serum.

PHYSIOLOGY

Action of Aldosterone on the Lachrymal Gland

THE lachrymal gland in mammals has acinar tissue leading to ducts lined with columnar epithelium showing no regional differentiation. The Na/K ratio of an established secretion shows no alteration in relation to variation in secretory rates, nor is there other evidence of sodium absorption from the acinar secretion associated with exchange for other ions[1]. There are no records of experiments on the effect of mineralocorticoids on the sodium–potassium relation of lachrymal secretion. In view of the fact that sheep were available with graded sodium depletion, and therefore proportional aldosterone secretion rate[2], saliva and tears were collected for sodium and potassium assay.

The sheep were Merino cross-bred. Four (two ewes and two wethers) had a parotid fistula from the start; a third ewe (Gretel) was used for two collections of tears over a fortnight and then a parotid fistula was made. Up to 450 m.equiv. sodium were lost daily from the fistulae and the degrees of sodium depletion were regulated by varying the amount of sodium bicarbonate solution given to drink[2]. Tears were collected by placing a 100-μl. capillary pipette at the lateral canthus of the eye and lachrymation was stimulated by blowing ammonia fumes at the conjunctiva. Precautions were not taken against evaporation because our interest was in the Na/K ratio. Parotid salivary samples were taken just before the tear collections. The sodium and potassium concentrations in each were estimated using a Beckman flame spectrophotometer.

Four animals were otherwise normal. The exception was Maxine, which had had bilateral Goldblatt clamps applied 12 months previously and had, at the time of the experiment, a systolic blood pressure of 150–180 mm mercury.

The results are shown in Table 1. This shows that the range of the Na/K ratio in tears is from 8·8 to 4·5, while that for saliva, which is known to reflect the degree of sodium depletion and aldosterone secretion[2], was from 41 to 0·58; in terms of concentration of potassium, there was variation by a factor of × 1·6 for tears and × 26 for saliva. The variation of lachrymal and salivary Na/K was not regularly concomitant, and it is likely that the variation of the potassium concentration of tears was due to the 'start-up' discharge of potassium at the onset of increased secretory rate which has been described for tears[3], for sweat[4,5] and for salivary glands[6–8].

As an extension of these results, it was decided to test the effect of aldosterone infusion in a sheep when sodium-replete and when sodium-deficient, in which latter instance the sensitivity of the parotid gland to aldosterone is increased[9]. Flora, a bilaterally adrenalectomized ewe, was normally maintained on 25 mg cortisone acetate and 5 mg DOCA daily. These hormones were withdrawn 36 h before experiments were performed. Tears and saliva were collected before and 150 min after the start of intravenous infusions of *d*-aldosterone at 20 μg/h.

Table 1 LACHRYMAL SODIUM AND POTASSIUM CONCENTRATIONS AND THE PAROTID SALIVARY Na/K OF FIVE SHEEP WITH SODIUM STATUS VARYING FROM REPLETE TO MODERATE TO SEVERE DEFICIENCY

Sheep	Salivary Na/K	Tears Sodium (m.equiv./l.)	Tears Potassium (m.equiv./l.)	Na/K
Gretel	(Before fistula)	162	19	8·5
		153	19	8·0
	41	140	17	8·2
	28	137	24	5·7
	6·1	141	27	5·2
	5 4	140	28	5·0
	1·06	142	20	7·1
Cecil	6·7	133	20	6·7
	4·0	144	23	6·3
	0 87	142	26	5·5
	0·58	127	28	4 5

	3·6	137	28	4·9
	0·85	152	27	5 6

Table 2. FLORA—THE LACHRYMAL SODIUM AND POTASSIUM CONCENTRATIONS AND THE PAROTID SALIVARY Na/K BEFORE INTRAVENOUS INFUSION OF *d*-ALDOSTERONE, AT 20 μg/H AND AFTER 150 MIN OF INFUSION, WHEN THE SHEEP WAS (1) SODIUM-REPLETE AND (2) SODIUM-DEFICIENT

Experiment	Salivary Na/K	Tears Sodium (m.equiv/l.)	Tears Potassium (m.equiv/l.)	Na/K
(1) Sodium-replete				
Before aldosterone	23·6	142	20	7·1
During aldosterone	5·9	132	27	4·9
(2) Sodium-deficient				
Before aldosterone	13·8	138	30	4·6
During aldosterone	1·6	130	23	5·6

The results in Table 2 are similar to the findings in sodium depletion (Table 1).

The lachrymal gland, in common with the pancreas and sublingual and palatine glands, does not show regional differentiation of ducts, and presumably does not have a sodium reabsorption and exchange mechanisms[1]. (Yoshimura and Hosokawa[10] state that lachrymal potassium increases proportionally to secretory rate and conclude that the gland actively secretes potassium without exchange for sodium or hydrogen. This behaviour would be different from that of the parotid, submaxillary and sweat glands in which, over a limited range, potassium decreases with increased secretory rate and sodium concentration. The conclusions of these authors should be accepted with caution because the high secretory rates occurred at the onset of increased secretion rates; constant secretory rates at several levels were not produced.) Because it shows trifling change in Na/K as compared with parotid saliva in sodium depletion and aldosterone infusion, and because such variation as does occur is not concomitant with the salivary variation and is explicable on grounds other than mineralocorticoid effect, it is reasonable to regard the gland as insensitive to aldosterone. A similar conclusion about the pancreas can be drawn from the observations that the potassium concentration of pancreatic juice did not rise in humans depleted of sodium by duodenal fistula[11]. In sheep the salivary Na/K of the palatine gland did not change in sodium depletion as did the Na/K of all the other salivary glands tested[12]. The insensitivity of these several glands to a level of aldosterone which has a large effect on the parotid and kidney[13] is consistent with the general proposition of Thaysen[6] that aldosterone may act at the sodium reabsorption and exchange mechanisms, but not at the acinar sodium secretory mechanisms.

Subcomponents of *PIII* in Cold-blooded Vertebrate Retinae

IT is generally accepted that the *PII* component of the vertebrate electroretinogram (ERG) arises in the bipolar cell layer. The origin of the *PIII* component, however, is still the subject of controversy. From experiments on the mammalian retina *in situ*, Brown and Wiesel[1,2] and Brown and Watanabe[3] conclude that the receptor cell layer is the origin of *PIII*, while Tomita[4], working on cold-blooded retinae, emphasizes the bipolar cell layer as the main origin of *PIII*. He observed more recently that, in the excised opened eye of the frog, a small fraction of *PIII* persists distal to the bipolar cell layer after the abolition of *PII* and the greater part of *PIII* by sodium azide. This suggests that *PIII* is made up of more than one component from different retinal layers[4]. This suggestion is strongly supported by our depth-recording experiment on isolated inverted retinae of cold-blooded vertebrates. The carp, frog and turtle were used with substantially the same result.

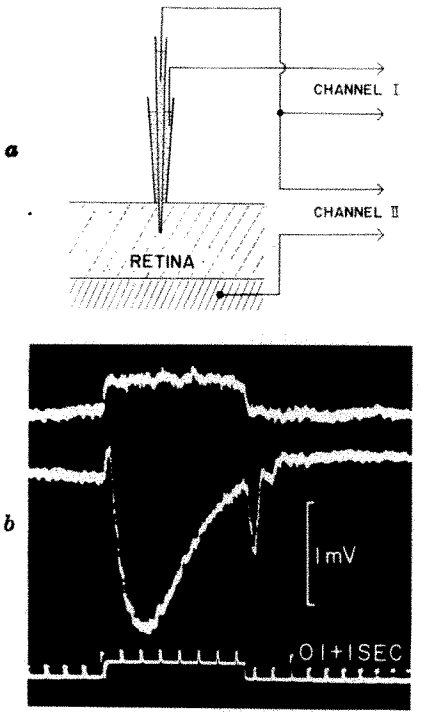

Fig. 1. (*a*) Experimental arrangement for depth recording of ERG with pencil-type coaxial microelectrode. (*b*) ERG of frog recorded with coaxial microelectrode. The inner pipette penetrated 120μ from the outer margin of the receptor layer, while the outer one was located on the receptor surface. The upper tracing shows the potential between the two pipettes (channel I in *a*) and the lower tracing shows the potential between the inner pipette and the indifferent electrode (channel II). Elevation of the time scale indicates the duration of illumination

After dark-adaptation, the retina was detached from the pigment epithelium and mounted with the receptor side up on a small piece of Ringer-soaked black paper, which thus constituted the indifferent electrode together with a chlorided silver plate underneath. The experimental arrangement is shown schematically in Fig. 1*a*: channel I records the potential between the inner and the outer pipette of a pencil-type coaxial micro-electrode, and channel II the potential between the inner pipette and the indifferent electrode. The outer pipette was located on the receptor surface throughout. These two potentials were displayed simultaneously on the screen of a dual-beam oscilloscope. All experiments were conducted at room temperatures of 18°–20° C.

Fig. 1*b* is an example of simultaneous recording in the frog through both channels with the inner pipette 120μ beneath the receptor surface. At this location of the inner pipette a sustained positive potential (which appears to correspond to the small fraction of *PIII* observed by Tomita[4]) was isolated after application of sodium azide on channel I at the largest amplitude and was little contaminated by *PII*. This will be called 'distal *PIII*', since it is located more distally than the remaining *PIII* fraction. It is clear from a large *a*-wave in the lower tracing (channel II) that the ERG thus recorded between the inner pipette and the indifferent electrode is made up not only of *PII* but also of a large fraction of *PIII*. This fraction of *PIII* has recently been localized in the bipolar cell layer[4,5] and will be called 'proximal *PIII*'. The distal *PIII* was maximal in amplitude at about 120μ in the carp and 80μ in the turtle. According to our histological measurement, the thickness from the outer margin of receptors to the outer plexiform layer is nearly 105μ in the frog, 120μ in the carp and 70μ in the turtle. The difference in depth for the maximal distal *PIII* was consistent with the difference in thickness of the receptor layer in the different animals. The following experiments provide evidence that these two *PIII* fractions are different in nature.

The distal *PIII* could be isolated from the proximal *PIII* by application for a few seconds of ammonia vapour from a fine nozzle placed near the retinal surface. As observed earlier, *PII* was most sensitive to this agent[6], and was the first component to be suppressed. The proximal *PIII* on channel II at this stage was larger than the *a*-wave in Fig. 1*b*, due apparently to decay of the *PII* component. By further application of ammonia, the proximal *PIII* was next abolished, while the distal *PIII* persisted, though slightly decreased thereafter in amplitude. The same result was obtained on all the animals used. A lower sensitivity to ammonia than any other ERG components of the distal *PIII* was one of the characteristics of the distal *PIII* sub-component. It is also suggested from the foregoing observation that the proximal *PIII* may be larger in amplitude than the distal *PIII*.

Another approach for discrimination of the distal *PIII* from the proximal one was to compare their latency using a data-processing digital computer ('*ATAC* 401' of Nihon Kohden Kogyo Co., Ltd.), which improved the S/N ratio. The inner pipette was located at the depth where the maximal distal *PIII* was obtained through channel I. This and the rest of the ERG through channel II were put into two separate channels of the computer which added 30–70 successive responses. The base-lines of both tracings were brought to the same level and their slopes were made equal by adjustment of amplifier gain in order to facilitate comparison of the latencies. The result on the frog is illustrated in Fig. 2, in which the tracing '*d*' indicates the start of the distal *PIII* and the tracing '*p*' that of the proximal *PIII* in the *a*-wave. The latency of the distal *PIII* is about 15 msec, being 7 msec shorter than that of the proximal *PIII*. Similar results were obtained on the carp and turtle; the distal *PIII* appeared 3–5 msec earlier than the proximal *PIII*. It is suggested that the distal *PIII* is a manifestation of a visual process that takes place earlier than other components, and probably reflects the process in the receptors themselves.

Intracellular recording in single invertebrate photoreceptors has been reported by many workers, but no work has been done on the vertebrate apart from a recent report on the single receptor potential in the carp by Tomita[7]. It seems reasonable to take this single receptor potential as the constituent of the distal *PIII*, since both of them are localized in the receptor layer. It is difficult to determine the exact ratio of the distal *PIII* to the proximal *PIII* either from the results of depth recording or by means of chemical agents, because of the difficulty of completely separating the two components.

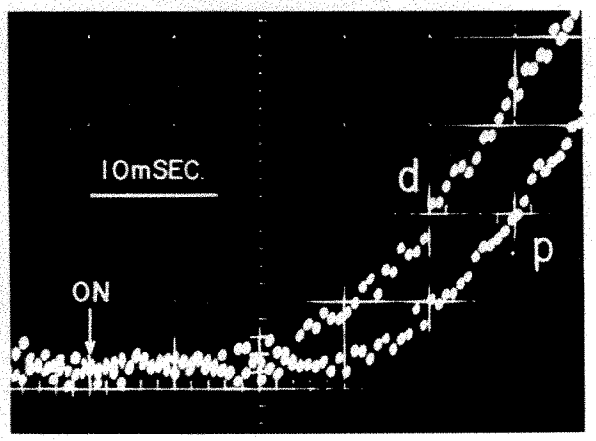

Fig. 2. Commencement of the distal *P*III (indicated as *d*) and the proximal *P*III (indicated as *p*), showing the difference in latency. Each of them was summed 70 times in a digital computer. Arrow indicates the beginning of illumination

PHARMACOLOGY

Drosophila-tests in Pharmacology

IN a communication under this heading, Lüning[1] has suggested a routine procedure by which potentially mutagenic drugs can be screened in tests on *Drosophila*. He uses developmental delay as the type of somatic damage that is likely to be correlated with whatever genetical damage has occurred. I wish to point out that in the only instance in which, to my knowledge, the effects of the same mutagen on developmental delay and mutation frequency were investigated, the correlation between them was clearly and strikingly negative. When larvae are raised on food to which formaldehyde at a low concentration has been added, high mutation frequencies are obtained so long as development proceeds at the normal speed. Any condition that delays development of the treated larvae—be this shortage of food, poor quality of food, supplementary harmful treatments, or even a more than optimal concentration of formaldehyde—concomitantly decreases mutation frequency[2]. For this particular mutagen, therefore, developmental delay would be a highly misleading guide to mutagenicity. It is, of course, possible that formaldehyde is exceptional in this respect, and that Lüning's test might be more reliable for other chemicals. Before this can be assumed, however, it will be necessary to establish experimentally for at least one member of the group of chemicals to be screened that its mutagenic action is positively correlated with its delaying action on development.

As an additional criterion for potential genetic damage, Lüning uses survival to adulthood, which for some of the drugs used by him went down as developmental time increased. This was also the case in most of the experiments with formaldehyde already mentioned. Since in these experiments genetical damage was negatively correlated with developmental delay, it was also negatively correlated with survival, more mutations being obtained at high than at low survival. In a number of cases it was, however, possible to destroy the parallelism between survival and speed of development, and in these it could be shown that the decisive factor in determining mutation frequency was developmental speed rather than survival. This was most clearly shown in one experiment where mutation frequency among the same batch of treated larvae was about twice as high in those flies that had developed with normal speed as in those that had reached adulthood after a developmental delay lasting 5–6 days. Conversely, in one experiment in which developmental delay had been prevented by the presence of dinitrophenol in the culture bottle, mutation frequency was not affected by a highly significant decrease in survival. It would seem, therefore, that decreased survival not correlated with delayed development might be a guide to genetical damage. This would agree with the findings by Müller's group[3] that X-ray-induced life-shortening in *Drosophila* is mainly caused by somatic chromosome loss. One way of demonstrating this consisted of the finding that, for a given exposure of larvae, survival decreased from females to rod-*X* males to ring-*X* males. Parallel results with a given drug would form strong presumptive evidence of genetic damage.

Synergistic Interaction of Kethoxal *bis*(Thiosemicarbazone) and Cupric Ions in Sarcoma 180

2-KETO-3-ethoxybutyraldehyde *bis*(thiosemicarbazone) [kethoxal *bis*(thiosemicarbazone); KTS], an agent that chelates metals of the first, second and third transition series[1], has been reported to be an inhibitor of the growth of several transplanted rodent neoplasms[2–5]. The antineoplastic potency of KTS was enhanced by the presence of either cupric or zinc ions[6]; however, the preformed cupric chelate was found to be the most potent of several different metal chelates of KTS[1,5,7]. To investigate the relationship of copper ions to the antineoplastic activity of KTS, the effects of combinations of cupric ions (as cupric chloride) and KTS, both on growth and on the synthesis of nucleic acids and proteins, were measured in sarcoma 180 ascites cells.

The tumour-inhibitory effects of such combinations on neoplastic growth were measured by determining the survival time of adult *Ha/ICR* Swiss mice inoculated with approximately 4×10^6 sarcoma 180 ascites tumour cells by intraperitoneal injection as previously described[8]. Therapy was initiated 24 h after implantation of the neoplastic cells and was continued for six consecutive days. The results obtained are shown in Table 1. Neither KTS in daily doses up to 60 mg/kg, nor cupric chloride in daily doses up to 10 mg/kg, increased the average survival time of tumour-bearing mice. In combination, however, significant prolongation of life was produced at low levels of each drug. No concomitant toxicity to the host was evident; thus, no weight loss from onset to termination of therapy was observed.

To probe for metabolic alterations associated with the growth-inhibitory potency of combinations of cupric chloride and KTS, the effect of a single dose of these agents on the synthesis of DNA, RNA and proteins was

monitored using thymidine-methyl-^{3}H, uridine-^{3}H and DL-leucine-1-^{14}C, respectively (Table 2). Little or no inhibition of these biosynthetic pathways was produced by either cupric chloride or KTS alone; however, combination of these agents caused about 82 per cent inhibition of the formation of DNA, 54 per cent inhibition of the synthesis of RNA, and a 62 per cent depression in the rate of formation of proteins. Although the magnitude of the effects of the combination on DNA were comparable with those produced by administration of the preformed cupric chelate of KTS, [Cu(II)KTS][9], the degree of inhibition of the synthesis of proteins by the mixture of copper chloride and KTS could not be explained by the formation of Cu(II)KTS *in vivo*. Furthermore, the magnitude of inhibition achieved by the mixture of cupric chloride and KTS could not be duplicated by appropriate quantities of Cu(II)KTS in combination with either KTS or cupric chloride[10]. Thus it would appear that cupric chloride, KTS and possibly some resultant Cu(II)KTS produce distinct alterations that result in synergistic inhibition of the synthesis of proteins.

Table 1. EFFECT OF COMBINATIONS OF CUPRIC CHLORIDE AND KTS ON THE SURVIVAL TIME OF MICE BEARING SARCOMA 180 ASCITES CELLS

Daily dosage* (mg/kg) Cupric chloride	KTS	Av. Δ wt.† (%)	Av. survival‡ (days)
0	0	+22·3	12·8 ± 0·5
0·5	0	+20·0	13·8 ± 0·8
1·0	0	+20·8	12·1 ± 0·8
0	2·5	+22·4	13·4 ± 0·6
0	5·0	+26·8	11·2 ± 0·9
0·5	2·5	+5·0	21·6 ± 1·3
1·0	5·0	+0·8	23·3 ± 1·7

* Drugs were administered intraperitoneally once daily for 6 consecutive days, beginning 24 h after implantation of tumour cells, with combinations given simultaneously.
† Average weight change from onset to termination of drug treatment.
‡ Each value represents the average survival time (± standard error) obtained with 9–20 mice.

Table 2. EFFECT OF CUPRIC CHLORIDE, KTS OR THEIR COMBINATION ON THE SYNTHESIS OF DNA, RNA AND PROTEINS IN SARCOMA 180 ASCITES CELLS

Treatment	Specific activity DNA*	RNA†	Protein
None	136·8 ± 10·6	13·05 ± 1·10	3,720 ± 147
Cupric chloride	109·9 ± 13·5	10·45 ± 1·35	3,380 ± 274
KTS	132·9 ± 11·8	8·55 ± 0·90	3,700 ± 147
Cupric chloride + KTS	25·2 ± 6·4	6·00 ± 1·05	1,420 ± 503

Six days after implantation of tumour cells, each mouse received a single intraperitoneal injection of either 2·5 mg of cupric chloride/kg body-weight, 50 mg of KTS/kg, or a combination of the two drugs administered simultaneously. Twelve h later an isotopic tracer was administered intraperitoneally to each mouse, and 1 h was allowed for incorporation. Isolations and analyses were performed as previously described (ref. 13).
* Determined as c.p.m./μmole of thymine × 10^{-3} after administration of 200 μg of thymidine-methyl-^{3}H ($5·7 \times 10^{3}$ c.p.m./μg) to each mouse. Each number represents the mean value (± standard error) obtained with 8–12 mice.
† Determined as c.p.m./mμmole of ribose after administration of 200 μg of uridine-^{3}H ($7·1 \times 10^{3}$ c p.m /μg) to each mouse. Each number represents the mean value (± standard error) obtained with four mice.
‡ Determined as c p.m /mg of residual protein after administration of 125 μg of DL-leucine-1-^{14}C ($1·45 \times 10^{4}$ c p.m./μg) to each mouse. Each number represents the mean value (± standard error) obtained with eight mice.

Table 3. COPPER CONTENT OF SARCOMA 180 ASCITES CELLS AFTER EXPOSURE TO CUPRIC CHLORIDE, KTS OR THEIR COMBINATION

Treatment	mμmoles Copper/g packed cells
None	9·2 ± 3·9
Cupric chloride	38·0 ± 4·4
KTS	10·2 ± 3·3
Cupric chloride + KTS	144·2 ± 29·1

Six days after implantation of tumour cells each mouse received a single intraperitoneal injection of either 2·5 mg of cupric chloride/kg body-weight, 50 mg of KTS/kg, or a combination of the two drugs administered simultaneously. Twelve h later ascites cells were wet-ashed and analysed for copper content as described by Stoner and Dasler (ref. 14). Each point represents the mean value (± standard error) obtained with four mice.

Since Cu(II)KTS, formed from the mixture of cupric chloride and KTS, is a relatively lipid-soluble form of copper and, therefore, would penetrate cellular membranes with comparatively greater ease than would copper ions derived from cupric chloride, the quantity of copper associated with the tumour cells after a single exposure to the drugs alone or in combination was determined (Table 3). The amount of copper/g of wet weight of cells was four times greater in sarcoma 180 cells removed from mice treated with cupric chloride than in untreated controls, whereas KTS did not significantly alter the copper content. Exposure of the neoplastic cells to the drug combination, however, resulted in a copper content 15·5 times that of untreated control cells. Although the large copper content of cells may be responsible for some of the observed biochemical effects, no direct correlation can be made between the quantity of copper found in the neoplastic cells and the degree of metabolic blockade[10].

The enhanced inhibitory effects observed in the present study with copper chloride and KTS are reminiscent of the synergistic chromosomal aberrations produced by combinations of ethyl methane sulphonate and copper ions in *Vicia faba*[11,12]. Investigations are now in progress to define precisely the enzymatic sites involved in the metabolic lesions produced by cupric chloride, KTS and Cu(II)KTS.

This research was supported by a U.S. Public Health Service Research grant from the National Cancer Institute. We thank Dr. H. G. Petering of the Upjohn Company, Kalamazoo, Michigan, for generously donating KTS and Cu(II)KTS, and Miss Sheila J. Feld for her assistance in performing these experiments.

Effect of Phytohaemagglutinin on Guinea-pig Skin *in vivo*

PHYTOHAEMAGGLUTININ (PHA) can stimulate the transformation of lymphocytes into lymphoblasts *in vitro*[1] and a therapeutic stimulant effect on haematopoietic tissue in aplastic anaemia has been claimed for it[2]. We have recently shown that PHA stimulates mitosis in the epithelial cells of the basal layer of adult human skin *in vitro*[3] using a system developed by us for short-term organ culture[4]. We now report the mitogenic effect of PHA on guinea-pig skin *in vivo*.

Three guinea-pigs (each weighing 500 g) were given a series of intradermal injections of PHA at 96, 72, 48, 24 and 4 h before they were killed. One ampoule of PHA-*M* (Difco Co.) was dissolved in 5 ml. Hanks's solution. The first guinea-pig was injected with 0·1-ml. volumes of this PHA solution, of a 1/10 dilution of this solution and of Hanks's solution. The second animal was given a similar series of injections, and 4 h before death received 0·75 mg desacetylmethylcolchicine ('Colcemid', Ciba, Ltd.) subcutaneously at a remote site. The third animal was given a series of injections of 0·1 ml. of (*a*) a mixture of PHA and 'Colcemid' containing an amount of PHA equivalent to that used in the other two animals and 125 μg of 'Colcemid', (*b*) 'Colcemid' solution (125 μg/0·1 ml.) and (*c*) Hanks's solution. Four hours before death 0·75 mg 'Colcemid' was injected subcutaneously at a remote site. Specimens from the injected sites and from normal control sites were fixed in 10 per cent formal saline immediately

after death and histological preparations were stained with haematoxylin and eosin.

Macroscopically, erythema and slight induration occurred at the sites where PHA had been injected at approximately 4 h, became maximal at 24 h and disappeared at 4 days. No visible change occurred at the sites of injection of Hanks's solution or of 'Colcemid'.

Microscopically, there was a marked thickening of the epidermis at the sites of injection of PHA after 4, 3 and 2 days with a lesser degree of acanthosis after 1 day. No acanthosis was seen at the 4-h injection site. Accompanying the acanthosis was a moderate cellular infiltration of the dermis by lymphocytes and polymorphs. A small fibrinous crust was seen overlying the horny layer at the PHA injection site. At the control injection sites a slight inflammatory infiltrate and crust were seen but there was no acanthosis. The acanthotic epidermis at the sites injected with PHA consisted of between eight and twelve cell layers compared with the two to four cell layers of the normal guinea-pig skin. The degree of acanthosis was proportional to the amount of PHA injected, the 1/10 dilution of PHA producing an acanthosis of three to six cell layers. At the sites injected with PHA there was also a thickening of the granular cell layer. This, as well as the acanthosis, diminished progressively away from the injection sites.

In the first guinea-pig there was a threefold increase in the proportion of the basal cells of the epidermis undergoing mitosis at the sites injected with PHA as compared to control sites. In the second animal 'Colcemid'-arrested metaphase mitotic figures occurred in 8 per cent of the basal cells at the sites injected with PHA as compared with 1 per cent at the control sites. In the third animal the range of 'Colcemid'-arrested mitoses at the sites injected with PHA was 6–16 per cent of basal cells compared with a range of 1–4 per cent at the control sites and at the sites injected with 'Colcemid' alone, on corresponding days.

These results show that phytohaemagglutinin has a mitogenic effect on epithelial cells of guinea-pig skin *in vivo*. They do not allow of any conclusions as to its mode of action. Recent work suggests that PHA stimulates the transformation of lymphocytes to lymphoblasts in culture by a direct action on their lysosome membranes[5,6]. This might also be the mechanism of the mitogenic effect of PHA on epithelial cells of guinea-pig skin *in vivo*.

HAEMATOLOGY

Magnesium, Adenosine Diphosphate and Blood Platelets

RECENTLY we reported[1] a relative plasma magnesium deficiency in a group of forty male patients with acute myocardial infarction (mean of 2·3 mg per 100 ml.) compared with thirty-six normal healthy males (mean of 2·6 mg per 100 ml.) in the same age group. In addition it was shown that magnesium added to fresh whole blood delays the clumping of platelets *in vitro*.

The ability of blood platelets to adhere to one another and form platelet clumps is well known, and work[2–4] on experimental animals has emphasized the part played by the intravascular clumping of platelets in the production of lung and heart lesions. The circumstances that lead to intravascular platelet clumping are still unresolved, but much interest was aroused by Hellem's[5] observation that a heat-stable extract of red cells, factor *R* (later identified as adenosine diphosphate[6]), could induce platelet clumping *in vitro*. More recently, Hovig[7] has shown the release of a platelet clumping substance, identified as adenosine diphosphate (ADP), from damaged platelets. Since Hellem's original observation, Born and Cross[8] and Silver, Stehbens and Silver[9] have induced intravascular platelet clumping in the cat and the rabbit by intravenous or intra-arterial injection of ADP, while Honour and Mitchell[10] report similar results in rabbits when ADP is applied to the outer surface of injured cerebral cortical arteries. In man, Davey and Lander[11] observed a temporary reduction in the number of circulating platelets after intravenous ADP, presumably due to the trapping of platelet clumps in small vessels.

This communication reports on the effect of magnesium on ADP-induced platelet clumping *in vitro* in human blood.

Blood was withdrawn by clean venepuncture into chemically clean siliconed needles and glassware and added immediately to one-fiftieth its volume of (*a*) 0·9 per cent saline alone; (*b*) varying concentrations of disodium salt of ADP (Boehringer Corporation, London, Ltd., or Sigma London Chemical Co., Ltd.) in isotonic saline or (*c*) varying concentrations of a mixture of magnesium chloride and ADP in isotonic saline. The blood was then centrifuged without delay for 1 min at 450*g* and 20° C and the supernatant examined microscopically every 5 min for the presence of platelet clumps, the size of which was determined by the use of a graticule. No anticoagulants were added to these blood samples at any stage. Poor withdrawals of blood were discarded.

Fig. 1 shows the platelet clumping activity of ADP *in vitro*. In general, ADP added to whole blood in a final concentration of 10^{-9} M (about 0·05 μg/100 ml.) does not have a noticeable clumping effect. Five times that amount is needed to cause clumping in whole blood. This clumping activity is a quantitative one, with larger platelet clumps occurring earlier and persisting longer with increasing concentrations of ADP. As platelet clumps occur in the supernatant of each sample, the number of discrete platelets diminishes. This feature is reversed in the biphasic curve produced with 5×10^{-8} M ADP in Fig. 1, when a decided increase in the number of discrete platelets is seen in the supernatant as the size of the platelet clumps become smaller between 15–30 min, with a dispersal of individual platelets from the large clumps. This transient platelet clumping activity with certain concentrations of ADP was also observed by Born[12] and O'Brien[13] using quite different experimental conditions. However, in their experiments this event was completed in 2–8 min using citrated plasma whereas here it takes 30 min. In the present series, when ADP is added in a final concentration of 10^{-7} M (about 5 μg per 100 ml.), massive platelet clumps of 1,000μ or more occur within 5 min and persist without lysis throughout the 35 min of the test period. Scarcely any discrete platelets are present in the supernatant.

It is of interest to note that the platelet clumping potency of commercially available ADP can vary from batch to batch so that quantitative comparisons are best carried out on pooled batches stored in a desiccator at 0° C. Solutions of ADP should be used within 2 h of preparation at room temperature.

Since concentrations of ADP in excess of 10^{-7} M cause the early lysis of platelets, 10^{-7} M was chosen as a suitably large final concentration of ADP with which to examine the influence of magnesium on platelet clumping. Fig. 2 shows the substantial reduction in the clumping activity of ADP in the presence of added magnesium. In addition to reducing the size of the platelet clumps it also reduces

their number and discrete platelets become more plentiful with increasing concentrations of magnesium. Magnesium at $0{\cdot}4 \times 10^{-3}$ M completely abolishes the effect of ADP and delays the clumping of platelets beyond that of the control blood.

It is important to realize the differences between our method and those of Hellem[14], Born[12], O'Brien[13,15] and others who used platelet-rich plasma obtained from anticoagulated blood of variable age. In doing so they exclude the influence on platelet behaviour of continuing metabolism in withdrawn blood, of the presence of red cells and of the effects of anticoagulants (such as citrate, ethylene diamine tetraacetic acid and heparin) on calcium and magnesium ions, enzyme systems and substrates. In fresh whole blood where electrolytes and enzyme systems are kept as near normal as possible, the platelets are at least twenty times more sensitive to ADP and its effect is much more prolonged.

In the present series of experiments the ADP is mixed with the magnesium before the addition of the whole blood, and it is possible that ADP is inactivated by magnesium before the blood is added. However, if the magnesium is first mixed with whole blood and then added to the adenosine diphosphate such a procedure might be expected to reduce the effectiveness of the magnesium, but it does not. Adenosine diphosphate is said to require the presence of ionized calcium before it will cause platelet aggregation[16,17] and Hellem and Owren[18] have proposed that ADP is bound to the platelet surface and to a second molecule of ADP by calcium, thus linking the platelets into an aggregate or clump. If the effect of magnesium is to reduce or prevent this activity at the surface of the platelet it is possible that its action might result from cation antagonism between magnesium and calcium[19].

We have already described[1] how the deficiency of plasma magnesium in patients with acute myocardial infarction might be easily replaced by taking orally an absorbable form of magnesium, for example, in the beverage 'Oxo'.

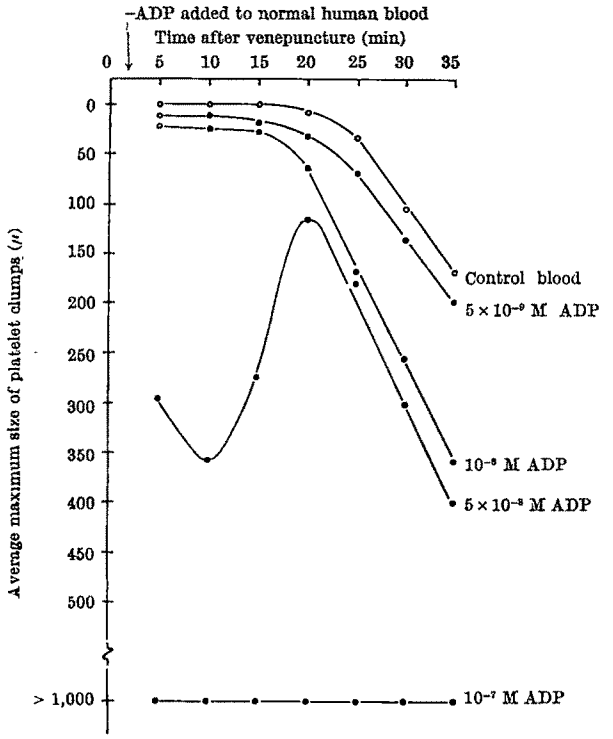

Fig. 1. Platelet clumping activity of adenosine diphosphate added to normal human blood *in vitro* in the absence of anticoagulants. Each point is the mean of eight to eleven results. The ordinate represents the average maximum size of platelet clumps (in μ) present in the supernatant of whole blood added to varying concentrations of ADP in isotonic saline (●——●) and in blood added to 0·9 per cent saline alone (○——○). The supernatant is examined microscopically every 5 min

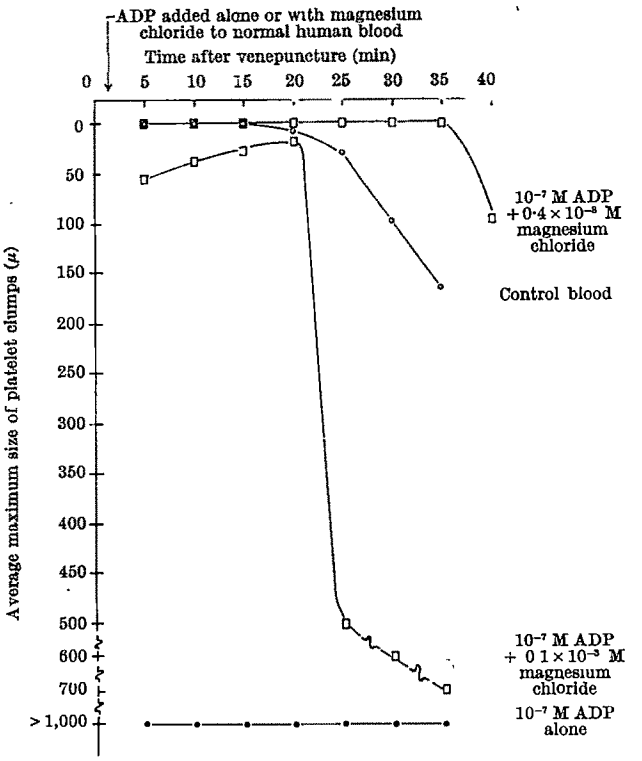

Fig. 2. The antagonism of the platelet clumping activity of adenosine diphosphate by magnesium in normal human blood *in vitro*. Each point is the mean of seven to eleven results. The ordinate represents the average maximum size of platelet clumps (in μ) present in the supernatant of whole blood added to mixtures of magnesium and ADP in isotonic saline (□——□), in blood added to ADP alone (●——●) and in blood added to 0·9 per cent saline (○——○). The supernatant is examined microscopically every 5 min

Final concentrations of added magnesium of 0·1 to $0{\cdot}4 \times 10^{-3}$ M (0·24 to 0·96 mg per 100 ml.) are within the range of supplements that would be needed to adjust to normal the low levels of plasma magnesium in patients with myocardial infarction.

Thus, if local increases of adenosine diphosphate play a part in intravascular platelet clumping these results suggest that magnesium might have a place in its antagonism.

IMMUNOLOGY

Graft-versus-host Specificity of Lymphoid Cells transformed from Bone Marrow Allograft in Supralethally X-irradiated Dogs

It has been shown that bone marrow allografts in supralethally X-irradiated dogs transform into lymphoid cells[1]. Soon after transplantation, so-called 'hyperbasophilic' cells may be observed in bone marrow punctures, and within 6–7 days they and transitional to small lymphocyte forms appear in great numbers in the peripheral blood. We have supposed that these lymphoid cells transformed from bone marrow stem cells are immunologically competent cells which are able to induce the 'graft-versus-host' reaction. This communication presents some evidence for this hypothesis. The participation of these cells in transplantation immunity was tested by their ability to induce a hypersensitivity reaction of the delayed type, called a 'transfer reaction' by Brent *et al.*[2].

Within 7 days of allogeneic bone marrow transplantation in dogs X-irradiated with a dose of 1,000 r., their own blood lymphocytes were injected intradermally into each dog. Leucocytes were isolated from 100–200 ml. of heparinized arterial blood, washed twice with medium 199 and resuspended in this medium to make up a count of nearly 5×10^7 per ml. 0·1 ml. volumes of cell suspension were injected into the lateral skin of the chest; two injections were normally made. In evaluating the reaction erythema, induration and swelling were taken into consideration, but the diameter of the skin lesion was considered the most important sign when scoring. The approximate scores given for the various diameters of the skin lesions were: +, (weak, 6–10 mm); 2+, (moderate, 11–15 mm); 3+, (strong, 16–20 mm); 4+, (21–25 mm); 5+, (very strong, 26–30 mm); and > 5+, (strongest, more than 30 mm). Reactions less than 2+ were considered as unreliable.

Five out of six animals demonstrated strong to strongest skin lesions within 18 h (see the upper part of Table 1). Surprisingly, in one dog the reaction was unreliable; other workers[2,3] have also noticed that not all experimental animals respond to immune lymphocytes. In one animal, the skin lesion presented a huge haemorrhage in the form of a circle with diameter 30 mm.

The immunological specificity of the reaction described is high. Lymphocytes tested in other dogs, intact or irradiated, either provoked moderate reactions (in about half the animals) or did not provoke any reliable reaction (see the lower part of Table 1). These strong skin lesions are therefore the result of a specific interaction between transplantation antigens and the immune lymphocytes committed against them. Some positive non-specific reactions may perhaps be explained by the presence of common transplantation antigens in pairs of animals selected at random. Nor can the possibility be excluded that immune lymphocytes quickly degenerate in the sites of injection, releasing some active substances which damage tissues non-specifically. It should be mentioned that, according to our unpublished data, these cells have a sharply decreased viability in tissue culture.

Table 1. Skin Reaction to Transformed Lymphoid Cells

Lymphocyte donors No.	Lymphocyte recipients No.	Leucocyte No. in injection ($\times 10^6$)	Percentage of lymphoid cells in injection	Reaction in 18 h
116	116	5·0	100	3+
118	118	4·8	97·5	+
139	139	5·0	100	>5+, 2+

154	,, 5	3·5	100	2+, 2+
156	,, 3	6·4	81	+, ±
159	,, 6	4·0	74	±, ±
159	,, 7†	2·4; 3·2	74	±, ±

* Thymectomized dog, 1,000 r. + bone marrow allograft.
† Dog survived 1·5 years after 1,000 r. + two bone marrow allografts.

Non-immune lymphocytes in amounts up to 4×10^6 provoked no reliable reaction either in autologous or in allogeneic injections both in intact and irradiated dogs. The latter fact again confirms the belief that the 'graft-versus-host' reaction is the only immunological component of the skin reaction provoked by tested lymphocytes in X-irradiated allografted dogs.

These experimental results support the hypothesis that the stem cells of bone marrow allografts in supralethally X-irradiated dogs transform into immunologically competent lymphoid cells which are directed against the transplantation antigens of the recipient. Such a transformation leads to interruption of the normal haemopoiesis of bone marrow allograft and removes its protective effect; the aggressive trend of the transformed cells against the recipient can only aggravate the recipient's radiation disease. The picture that we have observed in concentrated form in skin lesions can be expected to hold throughout the body, and it is a matter for speculation whether this reaction has a total diffuse character or is directed against certain 'targets'.

HISTOLOGY

Mitochondria in Odontoblastic Processes

The odontoblastic processes of human dentin are projections of the odontoblast cytoplasm into spaces in the dense collagenous, highly mineralized dentin matrix[1]. These projections can be up to several mm in length resulting in the cytoplasm being a long distance (2,000–3,000μ) from the odontoblast nucleus. The contents of odontoblastic processes in published electron micrographs have shown a varied appearance. In general they display a granular texture but do not contain recognizable cytoplasmic organelles[2–4]. Most of these specimens were prepared with standard osmium fixatives which have a very poor penetrating ability. We have investigated the ultrastructure of dentin fixed with glutaraldehyde which is particularly favourable for the preservation of membrane systems and has good penetrating ability. A freshly extracted tooth (severed from its blood supply no longer than 8 min) was broken into small fragments with at least one dimension 0·5–1 mm thick. These were immersed in cold fixative containing 1·25 per cent glutaraldehyde in *s*-collidine buffered to *p*H 7·4–7·55 and adjusted to a final osmolality of 360 milliosmols. Samples were post-fixed in 4 per cent osmium tetroxide for 48 h and then decalcified in a nitric acid–formalin mixture[5] for 12 h. They were then dehydrated in an alcohol series and embedded in 'Epon' *B* (ref. 6). Sections were cut with a diamond knife on an *LKB* 'Ultratome' and examined in an RCA *EMU*-3-*G* electron microscope.

Figs. 1 and 2 show sections of odontoblast processes from the root of an impacted lower left 3rd molar of a 26-year-old woman. The sections of processes were taken from a point midway between the cementum–dentin and the dentin–predentin junctions. The odontoblast cytoplasm contains (Figs. 1 and 2) mitochondria, membranous elements of endoplasmic reticulum and free and associated ribosome-like granules.

The mitochondria are spheroid, with a very distinct double membrane, and contain a variable number of inter-

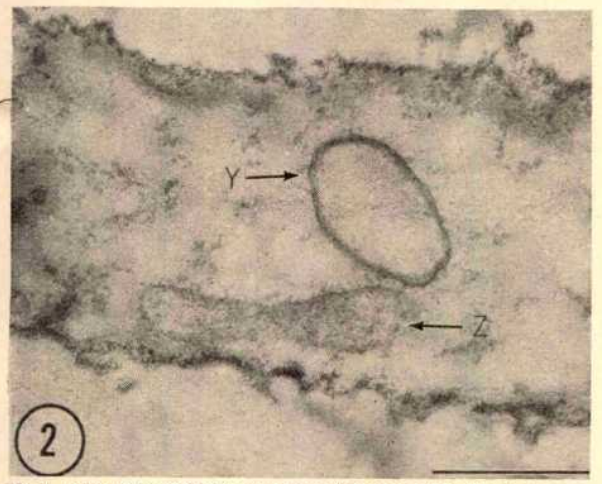

Fig. 1. Oblique to longitudinal section of human odontoblastic process. *C*, Dentin matrix; *M*, mitochondria; *R*, ribosome-like granules. Scale is 0·5μ

Fig. 2. Oblique to longitudinal section of human odontoblastic process. *Y* shows a vesicle surrounded by double membranes; *Z* shows a dumb-bell shaped structure surrounded by double membranes. Scale is 0·5μ

nal cristae. They range in size from 0·3 to 0·5μ in diameter. Occasionally one sees vesicles surrounded by double membranes but containing no cristae. These may be mitochondria either in the process of formation or degeneration. Fig. 2 contains a dumb-bell shaped mitochondrion suggesting the process of division.

Membranous elements of the endoplasmic reticulum are mostly in the form of cisternae. Ribosome-like granules are mostly associated into groups of strings with only a few free forms.

The presence of mitochondria and endoplasmic reticulum in the odontoblast processes of mature dentin suggests that there is considerable metabolic activity in the odontoblastic process cytoplasm even in those portions far removed from the odontoblast nucleus and even when they are encased in fully formed dentin matrix.

PATHOLOGY

Preservation of Trachoma Agent in HeLa Cells

UNLIKE most other members of the psittacosis-lymphogranuloma trachoma group, trachoma and inclusion blennorrhoea (TRIC) strains cannot usually be passed serially in cell cultures although they grow well in chick-embryo yolk-sac. A few TRIC strains have, however, been adapted to tissue culture, notably the T'ang strain, now designated TRIC/China/Peking-2/OT. Such strains may be useful when preparations free from contaminating yolk are needed. A limitation of the use of tissue culture strains is their lability on storage at low temperatures; survival of infective particles when frozen in tissue culture fluid is generally very poor.

The finding that cells can be successfully preserved at low temperatures in media containing dimethyl sulphoxide (DMS)[1,2] has been widely applied. It seemed possible that the infectivity of tissue-culture grown trachoma agents might be retained on freezing if the infectious particles could be preserved by this technique in their intracellular environment, that is, in inclusions contained in intact cells.

T'ang trachoma agent which had undergone at least six serial passages in HeLa cells was used. The suspending medium for freezing was Hanks's balanced salt solution without bicarbonate, with 0·5 per cent (w/v) lactalbumin hydrolysate and 25 per cent horse serum. Various concentrations of DMS were incorporated in this medium. Specimens were cooled to −50° C at the rate of approximately 1° C/min, using the device described by Nagington and Greaves[3]. Having attained −50° C ampoules were stored either with solid carbon dioxide or in liquid nitrogen. Infectivity of suspensions was titrated in HeLa cells[4] before freezing and after storage, and the percentage of the original infectivity surviving was calculated. Specimens were thawed at 36° C. Infectivity titres before freezing were generally between 10^6 and 10^7 inclusion-forming units per ml.

In several experiments, preservation of infectivity was found to be improved by freezing suspensions as intact inclusion-bearing cells rather than as particles liberated from the cells by ultrasonic treatment (Table 1).

To determine the optimal concentration of DMS for preservation of infectivity, replicate suspensions containing various concentrations of DMS were slow-frozen; infectivity remaining after storage in a solid carbon dioxide container was compared with that of the original suspension without DMS (Table 2). On these results 15 per cent DMS was selected as the optimal concentration in further experiments.

In these and in other experiments, infectivity was found to decline over a period of several weeks' storage in the solid carbon dioxide container. Infectivity surviving during carbon dioxide storage was therefore compared with survival on storage in liquid nitrogen (Table 3). After titration of an aliquot of infected cell suspension, replicate specimens were slow-frozen to −50° C. Some ampoules were then stored in carbon dioxide and some by

Table 1. PERCENTAGE INFECTIVITY OF TRACHOMA SUSPENSIONS SURVIVING AFTER 6 DAYS' STORAGE IN SOLID CARBON DIOXIDE

T'ang preparation	Basic medium plus	Rate of freezing	Percentage survival
Intact inclusions	No DMS	Rapid	8
Ultrasonic treated	15% DMS	1° C/min	29
Intact inclusions	15% DMS	1° C/min	67

Table 2. EFFECT OF DMS CONCENTRATION ON SURVIVAL OF INFECTIVITY

DMS percentage in medium	Percentage of infectivity surviving after carbon dioxide storage for 1 week	24 weeks
0	15	1
5	39	3

immersion in liquid nitrogen. Liquid nitrogen storage appeared definitely superior to storage in a solid carbon dioxide container, though lower levels of infectivity persisted for long periods on carbon dioxide storage. Other experiments confirmed the value of liquid nitrogen in preserving high levels of infectivity for the maximum 1 year testing period.

Freezing of intact inclusions at 1° C/min in medium containing DMS evidently much improves the survival rate, but slow loss of infectivity occurs on carbon dioxide storage. Temperatures in solid carbon dioxide containers undoubtedly fluctuate, and it is possible that infectivity would be better preserved if a temperature of −79° C were steadily maintained. However, thermodynamic changes are known to occur in biological materials at temperatures down to −130° C (ref. 5). Storage at −196° C proved more satisfactory for preservation of infective trachoma agent, though even at this temperature some enzyme systems are not completely stable[6]. In these experiments cell cultures were frozen at the end of one growth cycle, 40–42 h after inoculation. The inclusions then contain a high proportion of mature elementary bodies, but also many less mature forms. Of this varied population of particles presumably only the more resistant survive storage with solid carbon dioxide; a further proportion of particles, perhaps more labile, appears to be preserved in liquid nitrogen.

Small Virus-like Particles associated with Type *B* Virus Particles in a Transplantable Mammary Tumour of *ICR/Ha* Mice

THIS communication describes the electron microscopic appearance of small (20–55 mμ) virus-like particles which exist in a transplantable mammary tumour of *ICR/Ha* mice, and discusses the possible role of these particles.

A review of previous work on mouse mammary tumour virus, and a description of the appearance and development of *B* particles have already been given[1,2].

Mammary tumours of *ICR/Ha* mice were taken from the first recipients of a transplantable mammary tumour described previously[1]. Tumours were fixed in osmium tetroxide, embedded in 'Epon', stained with uranyl acetate and lead hydroxide, sectioned, and examined with an *EMU*-3 electron microscope.

A deliberate search was made for viral particles in the intermediate stage of development between maturing *B* particles[1] and the *A* particle. All the viral forms described herein were found in the cytoplasm of acinar cells. Many sacs were found which contained type *B* particles with eccentric nucleoids. The sacs ranged in diameter from small (about 380 mμ, Fig. 1), medium (about 1μ, Fig. 2) to large (about 3μ, Fig. 3).

In most sacs, small virus-like particles were present ranging in diameter from 20–55 mμ (Figs. 1, 2 and 3). A few of the small particles seemed to be attached to *B* particles (Fig. 3). Most of the small particles did not appear to be attached to the *B* particles, but were found singly or in groups throughout the sac. In a few cases, the particles were found outside of sacs in the cytoplasm (Fig. 1).

The small particles varied in appearance from that of a completely granular mass circular in shape at one extreme to a hollow ring with radiating spicules at the other extreme.

The significance of the existence of the small virus-like particle suggests the following five alternative possibilities. (1) It may be one form of the mammary tumour virus, possibly an infectious form. Particles of this size

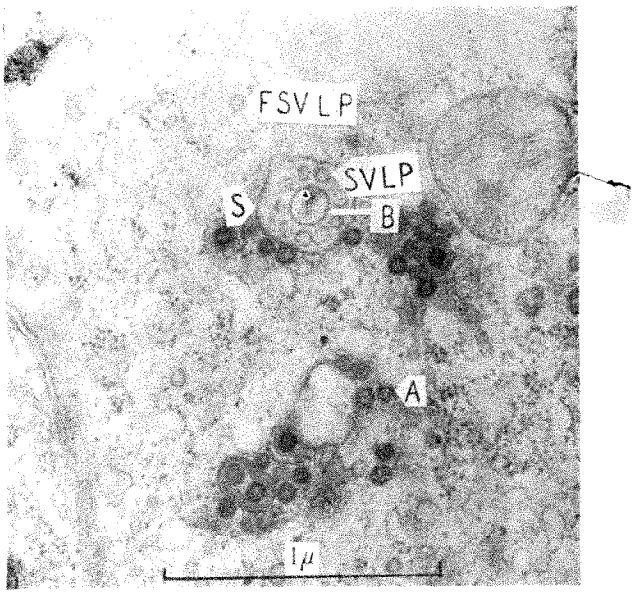

Fig. 1. Electron micrograph of cytoplasm of a transplantable tumour of *ICR/Ha* mouse. A single *B* particle (*B*) is located within a small sac (*S*). Small virus-like particles (*SVLP*) are seen between the *B* particle and the sac wall. A free small virus-like particle (*FSVLP*) is seen in the cytoplasm outside the sac. Numerous *A* particles are seen (*A*)

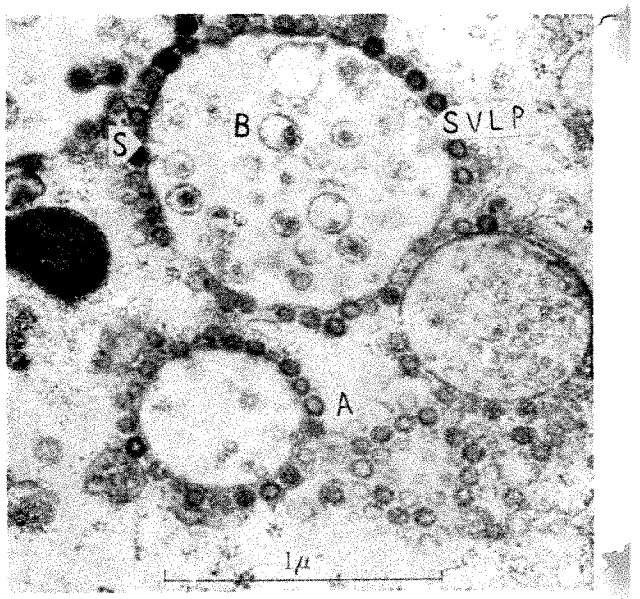

Fig. 2. Electron micrograph of cytoplasm of a transplantable tumour of *ICR/Ha* mouse. Numerous *B* particles (*B*) are present withir medium-sized sacs (*S*). Small virus-like particles (*SVLP*) can be seen within the sacs. Numerous *A* particles (*A*) can also be seen

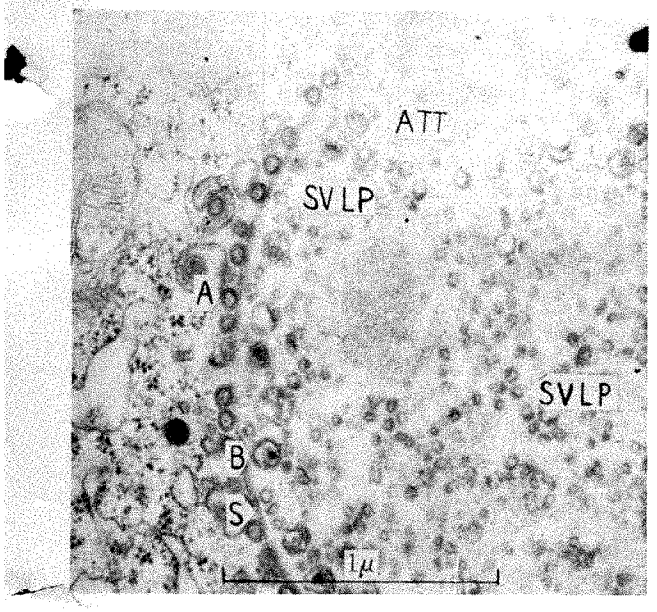

Fig. 3. Electron micrograph of cytoplasm of a transplantable tumour of *ICR/Ha* mouse. *B* particles (*B*) are present within the sac (*S*). Numerous small virus-like particles (*SVLP*) can be seen throughout the sac, and one appears to be attached to a *B* particle (*ATT*). Numerous *A* particles are also visible (*A*)

range were reported to be tumorigenic when separated from milk of mammary tumour strain mice by chemical extraction by Passey *et al.*[3], by filtration by Moore[4], and by irradiation by Moore[4]. Because of its size and location, it might be the precursor of the *A* particle. The presence of many *A* particles outside the sac in which many small particles are present is suggestive that this possibility should be investigated further. (2) It may be another mammary tumour virus not related to the *B* particle. (3) It may be a virus, but not one that will induce mammary tumours. (4) It may not be a virus, but a cell component arising at the site of viral infection. (5) It may be a normal cell component which is more obvious in vacuoles containing virus.

This work was supported in part by an institutional grant of the American Cancer Society. I thank Dr. Donald Henson for the light microscopic description of the tumours.

RADIOBIOLOGY

Radiation Dose Fractionation and DNA Replication

IT has been shown that the magnitude of depression of DNA synthesis following radiation can be altered by altering the dose-rate[1]. These preliminary results suggest that the total dose alone may be inadequate in the assessment of the effects of radiation on DNA synthesis. Dose-rate and the duration of radiation are additional factors which might be needed for an adequate assessment of the effects of radiation on this key biological process. This investigation was carried out on a synchronous population of hepatocytes, near the mid-point of the 8-h replication period following partial hepatectomy. A subsequent investigation was made into the dependence of DNA depression on dose-rate both in synchronous liver cells and in asynchronous cells of the first part of the small intestine[2]. These two series of experiments have permitted comparison of the effects of localized radiation on DNA synthesis both in synchronous liver cells and in asynchronous intestinal cells in the same animal. The curves describing the depression in the two organs were similar in character; however, the magnitude of the depression in the intestines, initially, was greater than in the liver.

Divided doses of radiation, comparable with those used by Elkind *et al.*[3], were used in an attempt to investigate the optimum time of delivery and the minimum dose of radiation needed to produce a maximum depression of DNA synthesis. Male, Lewis strain rats (200 g) were used and experimental conditions were similar to those used in previous investigations[4]. Radiation was given locally to the liver and adjacent intestines through a cone (3 cm in diameter) at a rate of 300 r./min, using 200 kVp. X-rays half value layer 1 cm copper; all radiation deliveries ended 21 h after partial hepatectomy. 50 μc. tritiated thymidine, 3 c./mmole in 1 c.c. normal saline, were given at the end of radiation, and the animals were killed 1 h later. Monolayers of liver cells were made by squashing random samples of finely minced liver. Fixation was carried out by freeze substitution, and all squashes were stained by the Feulgen technique, prior to the application of Kodak '*AR*-10' stripping film.

Two series of experiments were carried out on the effects of radiation on DNA synthesis after fractionated doses of radiation. The first series evaluated the effects of the fractionated dose (375 r. × 2) on cells of the liver, and the second series evaluated the effects of the fractionated dose (750 r. × 2) on cells of both the liver and the intestine of the same animal. The results are given in Table 1 and shown in Fig. 1.

The major depression of DNA synthesis in the (375 r. × 2) series occurred during the first 4 min. When the first dose was given 4–128 min before the second dose, the trend of DNA depression was slightly downward compared with fractionated doses within the first 4 min. The increase in the 256-min value, compared with the 128-min value, suggests that recovery may be beginning to take place between 128 and 256 min.

The major depression of synthesis occurred during the first 2 min in the 750 r. × 2 series. The liver cells showed almost no further change between 2 and 256 min. There is a much greater initial depression of DNA synthesis in the cells of the intestines compared with those of the liver.

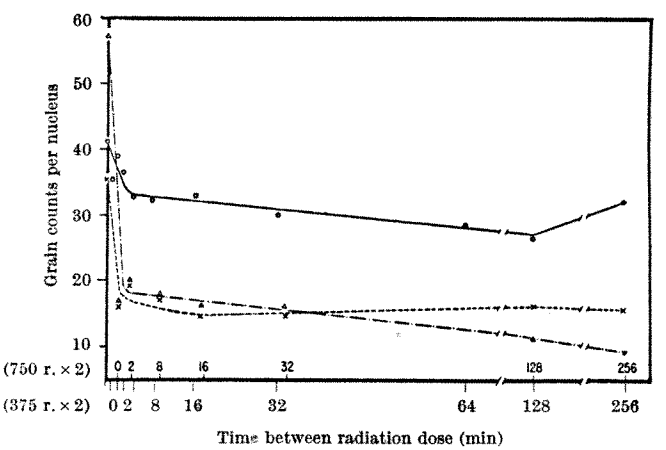

Fig. 1. Relation of radiation dose fractionation to the depression of DNA synthesis (liver and intestines, 21 h after partial hepatectomy). Zero time has been arbitrarily set as the time needed for the delivery of the single dose of 750 r. in the (375 r. × 2) series and for 1,500 r. in the (750 r. × 2) series. This is to separate the two experiments so that each can be graphically shown in the same figure. ○——○, 375 r. × 2 (liver); × - - - ×, 750 r. × 2 (liver); *Δ*— · — · —*Δ*, 750 r. × 2 (intestines)

± S.E.	3·4	1·9		0·9		4·7	2·2	1·5		1·0	1·1	

* 750 r. was given as a single dose. † 1,500 r. was given as a single dose.

The rate of synthesis is reduced to approximately half the control values in the liver and one-third of the control values in the intestines. The slight downward trend of DNA depression continues up to 256 min in both liver and intestinal cells.

It appears that the first few minutes are critical, since the major depression occurs within 4 min in the (375 r. × 2) series (liver), and within the first 2 min in the (750 r. × 2) series (both intestines and liver). The preliminary data suggest, therefore, that the optimum time of radiation delivery for the immediate depression of DNA synthesis is of the order of a few minutes.

This work was supported in part by a contract with the U.S. Atomic Energy Commission, the American Cancer Society and the U.S. Public Health Service.

BIOLOGY

Kiln-firing as a Technique for studying Nest-building Behaviour of Mud-dauber Wasps

IN a study of the utilization of mud by mud-dauber wasps, kiln-firing has been investigated as a technique for quick identification of the mud sources used by the wasps. *Sceliphron cementarium* (Drury) has been found to construct nests using radioactive mud from the waste disposal pits on the Atomic Energy Reservation at the Oak Ridge National Laboratory. *Trypoxylon politum* (Say) seldom used radioactive mud, although it nested in the same sites as *Sceliphron*[1]. Information about the kinds of mud used, and the sources of such muds, was necessary for interpreting the behaviour of the wasps in this unique situation.

Bartram[2] first reported the nests of these wasps as ". . . some curious wasp nests made of clay in Pensilvania", and later authors have stated that the nests are made of clay. According to the *Soil Textural Classification* used by the U.S. Department of Agriculture[3], none of the nests in the Oak Ridge area is made of clay. A textural classification of the nests is to be published elsewhere, but there is from 3 to 30 per cent clay in the mud used by the wasps. Mud-daubers, particularly *Sceliphron* females, tended to use mud from various sources in the construction of a single nest. Organic materials in the muds gave a nearly uniform colour to the nests, but kiln-firing revealed sharp differences in colour contributed by different clays.

Nests were removed from the field, placed in cold kilns at room temperature, and raised to 2,200° F either in 4 h or 12 h. The kiln-fired nests revealed strikingly the heterogeneous composition of the *Sceliphron* nests as the various clays came out in bright contrast (Fig. 1). Firing

Fig. 1. A live female *Sceliphron cementarium* (Drury) posed on a kiln-fired clump nest which shows the patchwork effect from the use of different muds by an individual of the species

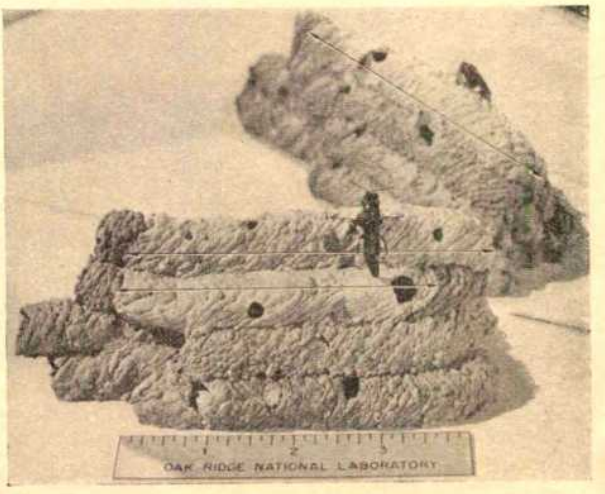

Fig. 2. A live female *Trypoxylon politum* (Say) posed on a kiln-fired pipe-organ nest which shows two tubes made of one mud (mirror image shows rear of one of these) with the remaining tubes composed of another mud

of the *Trypoxylon* nests showed clearly that this wasp is much more constant in its habits when bringing mud for nest construction. From Fig. 2 it can be seen that whole tubes of a *Trypoxylon* nest will be made of mud from a single source before there is a change to another source of mud. Moreover, *Sceliphron* often thickens the outside of the walls of its nests by plastering on balls of mud from a variety of sources (Fig. 1), whereas *Trypoxylon* does any thickening there may be on the inside. Fired *Trypoxylon* nests also reveal that the prepupal cocoon is composed primarily of grains of sand and clay chewed from the inner wall of the cell. The fired cocoon is white with localized spots of mineral colours derived from the clay it contains.

Some of the fired nests gave distinctive colours which were connected with a specific source, so that an estimate could be made of the flight range of the wasps. In a systematic study, kiln-firing would probably indicate the comparative usages by different species, seasonal changes in nest-building activity, and perhaps information about the rate of nest construction as well.

I thank Mr. Douglas Ferguson, of the Pigeon Forge Pottery, Pigeon Forge, Tennessee, for suggesting that kiln-firing might discriminate between different sources of mud.

Isolation of 2-Aminoethylphosphonic Acid from Phospholipids of the Abalone (*Haliotis midae*)

IN the course of an investigation of the phospholipids of the abalone shellfish (*Haliotis midae*), a ninhydrin-reactive substance was detected which showed properties similar to phosphoryl ethanolamine. For example, no separation between phosphoryl ethanolamine and the unknown compound was obtained by column chromatography on the cation exchange resin 'Amberlite *C.G.* 120' type 2 with an eluting buffer of *p*H 3·25. Hydrolysis with 2 N hydrochloric acid at 120° C for 100 h failed, however, to liberate ethanolamine and phosphoric acid. This substance was identified as 2-aminoethylphosphonic acid.

Horiguchi and Kandatsu[1,2] were the first investigators to describe the isolation of 2-aminoethylphosphonic acid from rumen protozoa and *Tetrahymena pyriformis W*. Recently, this compound has also been isolated from the sea anemone (*Anthopleura elegantissima*) in which it occurs free and esterified with glycerol and sphingosine[3–5]. It appears that the abalone is the highest organism in which the presence of this phosphonic acid has so far been demonstrated.

Lipids of the abalone (shell-free 3,800 g) were extracted with chloroform–methanol (2 : 1 by volume). The water-soluble impurities were removed by two washings according to Folch *et al.*[6]. After taking the material to dryness *in vacuo* it was taken up in petroleum ether (40–60° C) and filtered. The lipids (23·7 g; phosphorus 2·1 per cent), which were obtained after removal of the petroleum ether, were refluxed for 48 h with 600 ml. 6 N hydrochloric acid. The reaction mixture was filtered, the filtrate evaporated to dryness *in vacuo* and the residue taken up in about 20 ml. of water. The phosphonic acid was separated from other compounds by chromatography over a column of 'Zeokarb 225' (20 × 2 cm; 52–100 mesh, hydrogen form, 4·5 per cent divinyl benzene). The eluting agent was 0·1 N hydrochloric acid, 5 ml. fractions were collected and each fraction was tested for the presence of 2-aminoethylphosphonic acid by paper chromatography in 80 per cent *n*-propanol (R_F 0·10). One fractionation was insufficient, due to the presence of large quantities of choline, ethanolamine, serine, etc., and the separation was therefore repeated on an identical column. Fractions containing the compound (tube numbers 8–30 for the first separation and 50–100 for the second) were combined and evaporated to dryness *in vacuo*.

The resulting oil, which could not be induced to crystallize, was taken up in 2 ml. of water and transferred to a small column of 'Dowex 1–X8' (4 × 2 cm; acetate form). Elution was carried out with 0·5 N acetic acid; the first 20 ml. contained all the desired material. After evaporation of the acetic acid the material became crystalline. Recrystallization from 50 per cent ethanol gave 58 mg of 2-aminoethyl phosphonic acid, which melted at 284°–286° C and decomposed at 295° C. Horiguchi and Kandatsu[1] give 295°–297° C (decomposition); Kittredge, Roberts and Simonsen[3] give 280°–281° C (decomposition).

Authentic 2-aminoethylphosphonic acid was supplied by Dr. Horiguchi of the University of Tokyo. No depression in melting point was observed when mixing this substance and the isolated material; moreover, the infra-red spectra were identical. Horiguchi and Kandatsu[7] have recently shown dimorphism in 2-aminoethylphosphonic acid, resulting in two infra-red spectra. The substance described in this report corresponded to the metastable 'α-form' of these authors.

It was shown by column chromatography of the lipids on silicic acid according to Hanahan, Dittmer and Warashina[8] that the phosphonic acid was present in the phospholipids of the abalone. The phosphonic acid-containing lipid, which was eluted from the silicic acid column with chloroform–methanol 3 : 2 (by volume), emerged just before phosphatidyl inositol and phosphatidyl choline. This phospholipid fraction was very rich in sphingosine and it seems, therefore, that 2-aminoethylphosphonic acid is part of a sphingolipid, the structure of which is still to be established.

A complete report of the composition of the abalone phospholipids will be published elsewhere.

MICROBIOLOGY

Inability of Decenylsuccinic Acid to protect *Escherichia coli* against Damage by Freezing

CHEMICAL protection against injury due to damage by freezing has been extensively studied by various workers[1–6]. Recently Kuiper[9] reported that decenylsuccinic acid induced resistance to desiccation, cold and frost in young bean plants. When decenylsuccinic acid penetrates into the lipid layer of the membrane of bean root cells it increases water permeability. This permeability was only slightly temperature dependent[10]. Our laboratory has been interested in the protection against damage by freezing in bacteria[11]. We obtained samples of

decenylsuccinic acid from B. J. Humphrey, Humphrey–Wilkinson, Inc., North Haven, Conn., U.S.A., and investigated the activity of the compound in *Escherichia coli* cell suspensions exposed to sub-zero temperatures.

E. coli cultures were maintained in nutrient broth and in a chemically defined medium. 24-h cultures were used in the freezing experiments. Aliquots of decenylsuccinic acid were added to suspensions of *E. coli* containing approximately 1×10^7 cells/ml. and the preparations were frozen slowly at $-20°$ C. At intervals of 2, 4, 6, 8 and 10 days duplicate samples were removed from the freezer, quickly thawed in running tap water, and plate-counted. The thawed suspensions were decimally diluted, streaked in duplicate on nutrient agar plates with a bent glass rod, incubated at 37° C for 24–48 h and examined with the aid of a colony counter. The decenylsuccinic acid was dissolved in a few drops of hot ethanol, added to distilled water, and the slightly cloudy liquid was used. The experiments were repeated three times. I also performed experiments to rule out the toxicity of the chemical to *E. coli*.

E. coli frozen and thawed in the absence of decenylsuccinic acid resulted in a survival rate of 1·3 to 1·6 per cent. Cells frozen and thawed in various concentrations (ranging from 2·0 to 7·4 per cent) of decenylsuccinic acid resulted in a survival rate of 0·83 to 1·5 per cent. On the other hand, cells frozen and thawed in glycerol resulted in a survival rate of 11–15 per cent at the lower concentrations and up to 70 per cent at the higher concentrations (7·5 per cent) of glycerol.

This work indicated that decenylsuccinic acid was unable to protect *E. coli* against damage due to freezing measured in terms of colony-forming survivors.

Effect of Inositol on the Lipids of *Candida albicans*

PREVIOUSLY I have described[1] changes in the morphology and physiology of the cells of *Candida albicans* during early stages of growth. These changes are in part associated with the cell wall in that the cells are flocculant during the lag phase of growth. An analysis of the basic constituents in the cell wall and the variations in the constituents during growth have also been reported[2], and they indicate that the ability of the cells to flocculate might be due to a weakened cell wall during this stage.

Challinor *et al.*[3] reported the effect of inositol on the flocculation of *Saccharomyces cerevisiae*. These investigations indicated that inositol was a primary cell wall constituent, and in its absence the wall was weakened and the cells clumped together and formed aggregates (flocculation). Associated with these characteristics was an increase in the lipid content of the cells (but not the cell walls) and a possible reduction of the phosphorus in the cell lipids. Smith[4] similarly reported that *S. carlsbergensis*, when grown in a medium deficient in inositol, fails to properly divide and forms aggregates up to 50 cells. This communication describes the effects of added inositol to the growth, morphology, and lipid content of *C. albicans* during the flocculant stage of its growth.

The yeast was grown at 24° C in a medium consisting of glucose as the carbon source and ammonium tartrate and ammonium nitrate as the nitrogen sources. The only vitamin added was biotin. This medium is referred to as the defined medium. The supplemented medium consisted of the defined medium plus 10 mg inositol per 100 ml. medium. The cells were grown in flasks on a reciprocal shaker at a speed for maximum aeration for 12–21 h, the time of maximum flocculation, and then gathered by centrifugation, washed three times and freeze-dried.

The amount of growth obtained by the yeast in each of these two media was about the same. The yield (dry weight) of cells from 600 ml. of the defined medium was 3·72 g and that from 600 ml. of the supplemented medium was 3·94 g. Manometric measurements were made to compare the rates of aerobic respiration. The inositol-grown cells were found to possess the same respiratory rate as the cells grown on the defined medium. Microscopic examination indicated further similarities in the cells. The number of cells remaining attached following cell division appeared to be the same and the cells flocculated as well with the inositol as without.

The freeze-dried cells were treated with acetone to help the extraction of lipids by breaking lipid–protein bonds. The acetone was evaporated under nitrogen and the cells extracted with three treatments of a chloroform : methanol mixture (2 : 1 v/v) at room temperature. The three extracts from each cell type were combined, washed, and dried *in vacuo*.

Table 1. LIPIDS EXTRACTED BY CHLOROFORM : METHANOL MIXTURE (2 : 1 V/V) FROM CELLS OF *C. albicans* GROWN ON A DEFINED MEDIUM AND THE DEFINED MEDIUM SUPPLEMENTED WITH INOSITOL
(10 mg/100 ml.)

		Cells grown on defined medium	Cells grown on supplemented medium
Sterol esters	Weight (g)	0·3760	0·3284
	% Lipid	86·9	84·6
	% Cell	10·1	8·3

	% Lipid	3·1	2·7
	% Cell	0·4	0·3
Fatty acids	Weight (g)	0·0140	0·0100
	% Lipid	3·2	2·6
	% Cell	0·4	0·3
Phospholipids	Weight (g)	0·0246	0·0355
	% Lipid	5·7	9·1
	% Cell	0·7	0·9
Weight recovered lipids (g)		0·4326	0·3883
Dry weight of cells (g)		3·72	3·94

The lipid extracts were then fractionated by the technique of Fillerup and Mead[5] using a $2·2 \times 8·0$ cm column of silicic acid, and the sterol ester, triglyceride, sterol, fatty acid and phospholipid fractions separated by successive washes of 1 per cent diethyl ether in petroleum ether, 4 per cent diethyl ether in petroleum ether, 10 per cent diethyl ether in petroleum ether, 50 per cent diethyl ether in petroleum ether, and 25 per cent methanol in diethyl ether respectively. The results of these separations are shown in Table 1. Clearly, the greatest part of the lipid fraction of both types of cells is the sterol esters. The amount of triglycerides, sterols, and fatty acids is effectively the same in the two types of cells. However, the phospholipids are significantly increased in the cells grown in the presence of inositol. This increase in the phospholipids supports the findings of Challinor *et al.*[3]; however, the absence of inositol from the medium did not increase the total lipid content as he found but appears to have decreased it : 11·7 per cent lipid in the absence of inositol and 9·9 per cent with inositol.

The fatty acid fraction, the phospholipid fraction, and the combined fractions of the sterol esters, triglycerides, and sterols were analysed by gas chromatography for individual fatty acids. The fatty acids detected and their retention times are provided in Table 2. Differences in the fatty acid composition of the cells grown in the two types of media are found only in the combined fraction of sterol esters, triglycerides and sterols. Supplementing the growth medium with inositol did not alter the types of free fatty acids formed or the fatty acids in the phospholipid fraction. Differences in the fatty acids from the various silicic acid separated fractions are notable. The sterol ester–triglyceride–sterol combined fraction was transesterified by the anhydrous methanol–hydrochloric acid method of Stoffel *et al.*[6] to form the methyl esters of the fatty acids. Direct methylation of the free fatty acids and phospholipids was accomplished using the diazomethane method of Schlenk and Gellerman[7]. For the identification of the fatty acid methyl esters an *F* and *M* chromatograph (Avondale, Penn.) with a thermal conductivity detector was used. Conditions of the instrument were: injector temperature, 300° C; column temperature, 196° C; detector temperature, 360° C; the column, 6 ft. × ⅜ in., packed with 10 diethylene glycol succinate polymer in 'Celite' (60–80 mesh); and helium flow was 45 ml./min.

Table 2. FATTY ACID CONTENT OF SILICIC ACID-SEPARATED FRACTIONS OF LIPIDS OF *C. albicans* GROWN ON DEFINED (*D*) AND INOSITOL-SUPPLEMENTED (*S*) MEDIA

Presence of fatty acids determined by gas chromatography on a diethylene glycol succinate column at 190° C

* Values are listed as number of carbon atoms per number of double bonds.

† Relative to methyl myristate.

? Unidentified component or unclear peak.

The conditions affecting flocculation of *C. albicans* appear to be different from the effects on *Saccharomyces*. Where the lack of inositol in the medium weakens the cell wall, increases lipid content of the cell, alters the phospholipids of *S. cerevisiae*, and delays separation of the cells following nuclear division in *S. carlsbergensis*, only a decrease in the amount of phospholipids appears similar in *C. albicans*. However, the increased production of lipids and the changes in the fatty acids of the non-polar lipids indicates that a further investigation of the role of inositol in yeast lipid metabolism may prove valuable.

GENETICS

Sex-linkage of the Glucose-6-phosphate Dehydrogenase Gene in Equidae

ALTHOUGH the number of chromosomes in the diploid set varies from seventeen to eighty, placental mammals as a whole comprise one uniform group with regard to total genetic content[1–3]. Diverse speciation from the common ancestor, proto-insectivores, was apparently accomplished by re-arrangement of linkage groups and mutations of individual genes. The *X*-chromosome, however, appears to have escaped rearrangement. The *X*-chromosomes of a great majority of placental mammals, including man, cattle, the mouse, the dog, the horse, and the donkey, have been found to be almost identical in absolute size, comprising about 5 per cent of the genome[4]. This suggests that the primitive *X*-chromosome of proto-insectivores has persisted in its entirety in various placental mammals.

Glucose-6-phosphate dehydrogenase (G6PD) deficiency and G6PD electrophoretic phenotypes are sex-linked in man. In order to establish whether this is true in other animals, we studied the electrophoretic mobility of G6PD in the Equidae.

To prepare the haemolysate, red cells were washed after removal of buffy coat and a freeze–thaw haemolysate was prepared in 0·01 M potassium phosphate buffer, *p*H 7·0, containing ethylenediamine tetraacetate (EDTA) and β-mercaptoethanol. This buffer, which is quite stable at 4° C, contained 5 mg EDTA disodium salt and 0·1 ml. β-mercaptoethanol in each 50 ml.

Gel was prepared from 65 g hydrolysed starch and 500 mg disodium ethylenediamine tetraacetate (EDTA), which were mixed well in 500 ml. of 0·01 M potassium phosphate buffer, *p*H 7·0, and heated. Before de-gassing, 5 mg of triphosphopyridine nucleotide (TPN) monosodium salt in 1·0 ml. water was added to the molten starch, and the slurry was poured into an eight-channel electrophoresis tray as described by Smithies[5]. The tray was allowed to stand at room temperature for about 6–8 h. The slotter was removed and 0·05 ml. of the haemolysate, representing a 1 : 100 dilution of red cells, was placed in each slot. White petrolatum–mineral oil mixture (50° C) was poured over the slots to a thickness of 2–5 mm and about 1 in. to both sides of the slots. The whole surface was then covered with 'Saran Wrap' and placed vertically in the tray. Electrophoresis was carried out in a cold room at 4° C for 16–17 h at a gradient of 6–7 V per cm. The reservoir solutions consisted of 0·1 M potassium phosphate buffer, *p*H 7·0. The cathode compartment also contained 5 mg TPN in 500 ml. buffer.

Staining solution was prepared by a modification of a previously described spot-test reagent for G6PD (ref. 6); 10 mg glucose-6-phosphate (G6P) dipotassium salt (Sigma), 2 mg 3(4,5-dimethyl thiazolyl 1-2) 2,5-diphenyl-tetrazolium bromide (MTT), 2 mg phenazine methosulphate (PMS), and 2 mg TPN were dissolved in 10 ml. 0·1 M *tris* HCl buffer, *p*H 8·0, and poured over the sliced gel. The gel was then kept covered at room temperature for 30 min.

When left at room temperature for 30 min after the staining mixture was poured, two distinct bands were seen for all the animals tested. A third band, more slowly moving, was apparent only after more prolonged staining.

We sampled nine horses (a Shetland pony, an Arabian, a thoroughbred, and six ordinary horses), five male and four female; six donkeys, three male and three female; eleven mules, four male and seven female; and two hinnies, one male and one female—a total of 28 animals. (A mule is the offspring of a male donkey and a female horse; a hinny is the offspring of a male horse and a female donkey.) The electrophoretic mobility of the G6PD of male and female horses was the same, irrespective of breed.

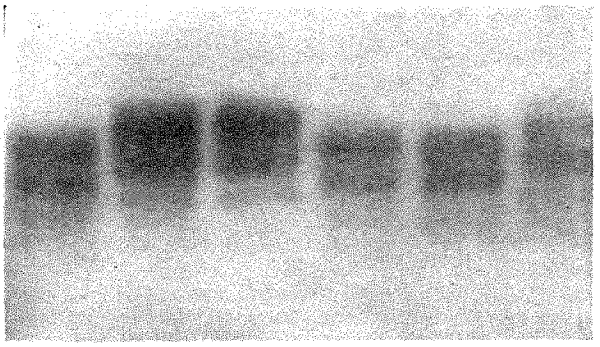

Fig. 1. The results of starch-gel electrophoresis of G6PD in Equidae. The following sources of enzyme were used: 1, male mule; 2, female donkey; 3, male hinny; 4, male horse; 5, male mule; 6, female donkey

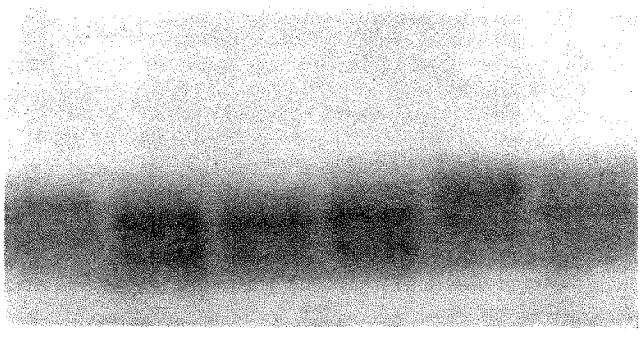

Fig. 2. The results of starch-gel electrophoresis of G6PD in an interspecies family group in Equidae. The following sources of enzyme were used: 1 and 5, male donkey (father); 2 and 4, male mule (son); 3 and 6, female horse (mother)

Male and female donkey enzyme had the same mobility, but the donkey enzyme bands were well ahead of the corresponding horse enzyme bands. All four male mules had G6PD bands identical with those from the horse. The male hinny had bands identical with those of the donkey (Fig. 1). Three of the female mules had G6PD bands like those of the donkey, two had bands like those of the horse, and two had bands of intermediate mobility. Female hinny bands resembled the horse bands. One family group was investigated. The results of electrophoresis of the G6PD of the father (donkey), mother (horse), and son (mule) are shown in Fig. 2.

In both types of crosses, the male offspring always showed the phenotype of the mother, verifying sex-linkage of the enzyme. The results of the electrophoretic determination on all twenty-eight animals are summarized in Table 1.

Sex-linkage of G6PD in man has been established by careful studies of pedigrees of kinships with G6PD variants which affect the electrophoretic mobility[7] or the activity of G6PD[8]. Young *et al.*[9] have presented data suggesting that G6PD is sex-linked in *Drosophila melanogaster*. However, since in this organism the *X*-chromosome comprises about 30 per cent of the genome, the presence of this gene on the *X*-chromosome may very well be fortuitous.

Table 1. G6PD PHENOTYPES IN EQUIDAE

Father	Mother	Offspring	Sex	No. of animals	Phenotype
Horse	Horse	Horse	♂	5	Horse
			♀	4	Horse
Donkey	Donkey	Donkey	♂	3	Donkey
			♀	3	Donkey
Horse	Donkey	Hinny	♂	1	Donkey
			♀	1	Horse
Donkey	Horse	Mule	♂	4	Horse
			♀	7	Horse, donkey, or intermediate

In view of the apparent morphologic stability of the *X*-chromosomes in mammalian species, it appeared to be of special interest to test the homology of sex-linked genes among various placental mammals. Haemophilia A and B, both sex-linked in man, have already been shown to be sex-linked in the dog as well[10,11]. A sex-linked mutation analogous to anhydrotic ectodermal dysplasia of man has been found in cattle[12]. Our finding that G6PD in the red blood cells of the donkey and the horse had different electrophoretic mobilities provided us with an opportunity for examining possible sex-linkage of the gene for this enzyme in Equidae.

If G6PD is sex-linked, the male interspecific hybrid receiving his only *X*-chromosome from his mother should manifest the same phenotype as the mother. As shown in Table 1, this is always the case. In the female hybrid, either the maternal, the paternal or a mixed phenotype might be expected, since it has been established that the locus for G6PD is involved in inactivation of the female *X*-chromosome[13–15].

This study clearly demonstrates the localization of the gene controlling G6PD phenotypes to the *X*-chromosomes in Equidae[16]. Investigations are under way to determine whether other interbreeding species may have different electrophoretic phenotypes, so that the possibility of sex linkage in such species may be explored.

This investigation was supported in part by the National Heart Institute and the National Cancer Institute, U.S. Public Health Service.

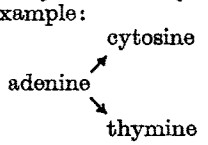
Amino-acid Substitutions in Haemoglobins and the Mutation Process

VARIOUS genetically determined human and animal haemoglobins differ in the amino-acid sequences of their polypeptide chains[1,2,6]. On the basis of the ribonucleic acid triplets published recently[4,5] all abnormal human haemoglobins which are due to single amino-acid substitutions can be explained by single base pair changes in the deoxyribonucleic acid. Comparing the normal human β- and δ-chains we found that only the exchange of threonine to glutamine in position 87 (1 of 10) cannot be interpreted by a single point mutation.



Comparison of the β-chains of man, gorilla, horse, and pig showed that only 4 (of 18) amino-acid substitutions cannot be due to a single base substitution.

Many of the amino-acid exchanges between the normal α- and β-chains, on the other hand, are most probably not caused by single point mutations.

Since the genetic code is a degenerated one, several codons for every amino-acid are possible[4,5]. On the grounds of base pair changes in haemoglobin genes (Table 1) some of these codons can be excluded for certain positions. Exclusions by abnormal haemoglobins are more certain than those based on comparison of β- and δ-changes or of β-chains of different species, since the occurrence of a single point mutation must be assumed.

The base pair changes can be divided into transitions and transversions[2]. Transitions are substitutions of a purine (pyrimidine) base by another purine (pyrimidine) in the DNA, whereas transversions are substitutions of a purine by a pyrimidine or vice versa.

Every base has only one possibility for a transition (adenine ⇌ guanine, cytosine ⇌ thymine), but two for transversions; for example:

Therefore we have altogether four possible transitions and eight possible transversions. If replacement was a random occurrence we should find twice as many transversions as transitions. Instead, however, there are more transitions than transversions (Table 2). The difference from that expected under an assumption of randomness is statistically significant ($P \ll 0{\cdot}0027$).

Table 1. RESTRICTION OF CODONS

Position and amino-acid	Possible codons	Impossible codons	Information
	(*a*) In the β-chain		
12 Thr	TGA, TGG	TGT, TGC	β→δ
16 Gly	CCA, CCG	CCT, CCC	β-Comparison Abnormal Hb
20 Val	CAT, CAC	CAA, CAG	β-Comparison
67 Val	CAT, CAC	CAA, CAG	Abnormal Hb
125 Pro	GGT, GGC	GGA, GGG	β→δ
126 Val	CAT, CAC	CAA, CAG	β→δ
70 or 76 Ala	CGT, CGC	CGA, CGG	Abnormal Hb
	(*b*) In the α-chain		
15 Gly	CCA, CCG	CCT, CCC	Abnormal Hb
22 Gly	CCA, CCG	CCT, CCC	Abnormal Hb
57 Gly	CCA, CCG	CCT, CCC	Abnormal Hb
	(*c*) In the δ-chain		
22 Ala	CGT, CGC	CGA, CGG	β→δ
116 Arg	GCA, GCG	GCT, GCC	β→δ

Table 2. UNEQUIVOCAL BASE PAIR CHANGES

Types of changes		Abnormal human haemoglobins	β→δ	β-comparison	
Transitions	A→G	—	—	1	
	G→A	3	—	—	
	T→C	5	1	3	
	C→T	11	1	2	Sum: 27
Transversions	A→T	1	1	2	
	T→A	1	1	—	
	G→C	2	—	—	
	C→G	2	—	—	
	A→C	—	—	1	
	C→A	—	1	—	
	G→T	1	3	—	
	T→G	2	1	—	Sum: 19

A special examination shows, on the other hand, that the four bases have about equal probabilities of being involved in the mutation process.

There are two possible explanations for the higher frequency of transitions: either amino-acid substitutions caused by transitions are less deleterious for the haemoglobin molecule than changes caused by transversions, or transitions really do occur more frequently because of steric similarity within the purines and the pyrimidines respectively.

The latter hypothesis is supported by the observation that transitions predominate in rare haemoglobin variants observed in recent populations more than in the δ- and β-substitutions which are characteristic of older populations. Arguments for this hypothesis will be presented in greater detail elsewhere[7].

PSYCHOLOGY

Cross-modal Transfer of Conditional Discrimination Training in Monkeys

IN previous work monkeys were trained to discriminate accurately between two test-objects in one sense modality, say by touch. Their performance was then assessed when the same two objects were later presented for discrimination in another sense modality, say by vision. If their performance in the second (visual) modality was better than that of an appropriate control group of animals without previous (tactile) experience of these objects, cross-modal transfer of training has occurred. Recently the findings in such experiments and their implications for theories of perception and language were discussed in detail[1]. It was concluded that only in one investigation[2] with monkeys was there evidence of significant positive cross-modal transfer of training related to an individual discrimination habit. However, in that investigation[2], only one of four comparisons attained statistical significance. On replication with eight instead of six animals the same trend was found as before but no comparison reached statistical significance (personal communication from M. Wilson).

Different results were obtained when cross-modal transfer of a learnt principle (instead of a specific habit) was sought. Monkeys were trained on a series of thirty or more discrimination problems in the first sense modality. Their performance improved over this series of problems, even when nothing specific about the test-objects in one problem could be transferred to succeeding ones. The animals thus acquired a 'learning set' or, in the present terminology, learnt a principle in the first modality. When their performance was assessed on comparable problems in the second modality, a small but consistent cross-modal transfer effect (most recently measuring 3·5 per cent) was demonstrated[3] for this improvement at learning discrimination tasks.

In the present experiment we trained monkeys to perform accurately at a conditional discrimination task in one sense modality. Later we looked for transfer when the same task was given in another sense modality. With such conditional training the animal does not merely learn to make a particular stimulus-reward association (as it might be said to do in learning a specific discrimination habit): on some trials it learns to select the one test-object, on other trials it selects the second test-object, depending on the nature of a third 'conditional' feature possessed by both of the test-objects. Therefore in conditional training the animal learns a task having characteristics in common with both a principle and a specific habit.

Our subjects were eight adolescent rhesus monkeys, approximately matched in pairs. Animals 1, 2, 3, 4, 7 and 8 had participated (as animals *C*1, *C*2, Pre-str 1, Pre-str 2, *C*5 and *C*6, respectively) in an earlier investigation[4]. Animals 5 and 6 were untrained at the beginning of this experiment (except that each had learnt one tactile

Table 1. PERFORMANCE SCORES ON CONDITIONAL DISCRIMINATION TASK GIVEN IN TWO SENSE MODALITIES

Animal		1	2	3	4	5	6	7	8
Tactile									
Preliminary training to 20 correct in 30 trials, both heights	Trials	370	160	140	140	100	190	80	360
Alternately tall and short, to criterion	Trials	724	153	212	334	40	458	811	2,000*F*
	Errors	224	39	26	65	1	82	293	786
	Reversals	14	6	15	12	4	17	9	14
Reversal of polarity of reward									
Visual		Yes	No	Yes	No	Yes	No	No	
Percentage of correct responses in first 50 trials		48	50	50	64	50	54	66	
Alternately tall and short, to criterion	Trials	1,050	1,250	985	365	573	777	1,147	
	Errors	390	576	358	231	202	212	458	
	Reversals	16	8	12	7	13	23	13	
Reversal of polarity of reward									
Tactile		No	Yes	No	Yes	No	Yes	Yes	
Percentage of correct responses in first 50 trials		32	36	46	20	40	18	38	
Alternately tall and short, to criterion	Trials	1,849	380	322	909	260	890	965	
	Errors	773	205	108	301	98	319	416	
	Reversals	17	6	10	26	7	20	13	

Animals 1–4 were trained by one experimenter, animals 4–8 by another. The figures in the body of the table refer to the number of trials required to attain the criterion for conditional training stated by Chow (ref. 5); or the number of errors made in attaining this criterion; or the number of reversals made within one sense modality (that is, between tall and short rods) in attaining this criterion. The letter *F* for animal 8 indicates that it failed to meet the appropriate criterion within the stated number of trials.

object discrimination task, cylinder and sphere, in 230 and 280 trials, respectively). Training was carried out in standard apparatus[4] and with standard procedure for conditional tasks[5]. Forty trials were given daily, 5 days each week. The test-objects were four metal rods, set vertically on the lids of the food containers. The rods were either tall (4·8 cm) or short (1·1 cm); and also either fat (3·1 cm diameter) or thin (1·1 cm). For all animals two tall (or short) rods were presented concurrently, and choice of the thin (or fat) rod was rewarded. Each of the four pairs of animals received a different one of the four training conditions initially. Therefore, disregarding order of training, two pairs of animals learnt to select the thin rod if both rods were tall and the fat rod if both were short; the other four animals learnt to select the fat rod if both were tall, the thin rod if both were short. For tactile training in the dark, the animals were able to grasp the rods directly in pushing the lids; for visual training in the light, the rods were enclosed in standard transparent plastic cylinders. (Control procedures undertaken at the end of the main experiment demonstrated that all animals, except possibly animal 6, responded to the rods rather than to minor differences in the cylinders during visual training. Animal 6 gave ambiguous results.)

The sequence of training and the results are shown in Table 1. All animals were trained first in the dark, then in the light and finally once again in the dark. Following the design of an earlier investigation[2] the polarity of reward was reversed for one animal in each pair after changing from the first to the second sense modality, and for the other animal of that pair after changing back from vision to touch. With this design it was possible to compare 'reversal' animals with 'non-reversal' animals after two changes of sense modality. (Polarity of reward is said to be reversed when an animal that was trained in the first modality to select the thin rod if tall and the fat rod if short is trained in the new modality to select the fat rod if tall and the thin rod if short.) Animal 8 failed to reach the standard level of performance within 2,000 trials of training in the first sense modality. Therefore transfer results are available for only seven animals.

Various measures of performance have been used: (1) percentage of correct responses in the first fifty trials after a change in modality; (2) the number of trials required to reach criterion in the new modality; (3) the number of errors made in reaching criterion in the new modality. For the change from tactile to visual training (comparing three reversal animals with four non-reversal animals) there is no clear evidence of significant cross-modal transfer ($P = 0{\cdot}057$, 0·429 and 0·314 for the three stated measures, respectively). For the opposite change from vision to touch (comparing four reversal animals with three non-reversal animals) a similar result is found ($P = 0{\cdot}114$, 0·314 and 0·314, in all six comparisons using the Mann–Whitney test). Combining the two changes in sense modality and comparing the percentage of correct responses in the first fifty trials for six pairs of animals, there is again no significant difference between non-reversal and reversal animals ($P = > 0{\cdot}05$, Wilcoxon matched-pairs signed-rank test). A fourth measure of performance is shown in Table 1, namely reversals within one sense modality to criterion (that is, between tall and short rods); however, this measure correlates highly with the other measures, so that statistical analyses are not reported.

After completion of the main experiment, animals 2, 4, 6 and 7 were tested alternately or randomly (trial by trial) in the light and dark, but always using the rods without the plastic cylinders as for tactile training. Although opposite responses were required depending on the presence or absence of light (since the polarity of reward had been reversed for these four animals between visual and tactile training), all four animals performed at levels of 90 per cent correct responses or better without further training.

We have thus found no clear evidence of cross-modal transfer of conditional training in monkeys. It is noteworthy that we did find a weak and non-significant initial cross-modal effect for the first change of sense modality. With a similar measure (errors in the initial trials), Wilson and Shaffer[2] obtained a significant effect at this stage of their experiment. This effect is not so apparent in their or our results using other measures; nor is it evident using the same measure after the second change of sense modality in either study. Our negative findings confirm previous work with monkeys on specific discrimination habits acquired by vision and touch[6] or by vision and hearing[7]. Since significant transfer of learnt principles has been reported in monkeys[3] we conclude that learning a conditional task resembles more closely the formation of a discrimination habit than the acquisition of a principle. Moreover, in terms of brain function, we suppose that individual neural systems are concerned when the same test-objects are presented to the monkey for tactile and visual learning. These conclusions emphasize the important role of language as a cross-modal bridge in man.

INSTITUTION OF ELECTRICAL ENGINEERS, ELECTRONICS DIVISION (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. B. R. Webster: "Teaching by Television".

SOCIETY OF CHEMICAL INDUSTRY, COLLOID AND SURFACE CHEMISTRY GROUP (at 14 Belgrave Square, London, S.W.1), at 5.30 p.m.—Annual General Meeting, followed by Dr. L. Golberg. "Biological Attributes of Synthetic Surface-Active Compounds in the Animal Organism".

PLASTICS INSTITUTE, LONDON SECTION (at the Wellcome Buildings, Euston Road, London, N.W.1), at 6.30 p.m.—Symposium on "Powders".

SOCIETY FOR ANALYTICAL CHEMISTRY, AUTOMATIC METHODS GROUP (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 6.30 p.m.—Meeting on "Sample Handling Techniques".

Wednesday, April 6

COLOUR GROUP (GREAT BRITAIN) (at Imperial College, London, S.W.7), at 2.30 p.m.—Mr. I. J. P. James: "The Separate Luminance Colour Television Camera"; Mr. C. B. B. Wood: "Consideration in the Design of Colour Television Cameras"; Mr. W. N. Sproson: "Colorimetric Aspects of 3 and 4 Tube Colour Television Cameras".

GEOLOGICAL SOCIETY OF LONDON (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Dr. M. G. Audley-Charles: "The Geology of Portuguese Timor", Dr. G. Y. Craig and Dr. G. Oertel: "Deterministic Models of Living and Fossil Populations of Animals".

ROYAL MICROSCOPICAL SOCIETY (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Prof. A. G. E. Pearse: "Developments in Enzyme Histochemistry".

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

MASTER to teach Chemistry to Advanced and Scholarship Level—The Warden, St. Edward's School, Oxford (April 7)

LECTURER IN MATHEMATICS—The Principal, Avery Hill College, Bexley Road, Eltham, London, S.E.9 (April 8).

PRINCIPAL LECTURER (with an honours degree in botany and considerable teaching and research experience), and a LECTURER (with an honours degree in botany) to teach Botany—The Principal, West Ham College of Technology, Romford Road, Stratford, London, E.15, quoting Ref. RAW/JA/635/3 (April 8).

EXPERIMENTAL OFFICER (with a university degree or equivalent and preferably practical experience of the semiconductor field) IN THE DEPARTMENT OF ELECTRICAL ENGINEERING IN THE FACULTY OF SCIENCE to assist research work on electro-luminescence in semiconductors and related phenomena—The Registrar, The University, Manchester, 13, quoting Ref. 54/66/Na (April 12).

LECTURER (preferably with a special interest in analytical chemistry) IN THE DEPARTMENT OF CHEMISTRY (Inorganic and Analytical)—The Secretary, The Queen's University, Belfast, Northern Ireland (April 13).

LECTURERS or ASSISTANT LECTURERS IN CHEMISTRY (there are vacancies in all branches of the subject, including new developments in chemical physics)—The Registrar, The University, Manchester, 13, quoting Ref 38/66 (April 13).

EXPERIMENTAL OFFICER (interested in the design and construction of equipment for a wide range of psychological experiments, and preferably a knowledge of electronics)—The Registrar, The University, Manchester, 13, quoting Ref. 58/66 (April 14).

EXPERIMENTAL OFFICER (with a university degree or equivalent qualification and preferably a knowledge of chemistry) IN THE DEPARTMENT OF PHYSICS OF THE FACULTY OF SCIENCE, to run an evaporation and target construction laboratory in the Nuclear Physics Section of the Department—The Registrar, The University, Manchester, 13, quoting Ref. 53/66/Na (April 14).

ASSISTANT LECTURER or LECTURER (with a registrable qualification in veterinary medicine or an honours degree in pharmacology, or a related subject) in the Department of Veterinary Pharmacology, Royal (Dick) School of Veterinary Studies—The Secretary, The University, Edinburgh (April 15).

LECTURER or SENIOR LECTURER (honours graduate, preferably with a knowledge of the economic aspects of tropical entomology) IN ENTOMOLOGY; and a SENIOR LECTURER (honours graduate, preferably with a doctorate and teaching and/or research experience at university or equivalent level) IN BIOCHEMISTRY at the University of Nigeria, Nsukka, Eastern Nigeria—The London Representative, University of Nigeria, 33 Craven Terrace, London, W.2 (April 15).

LECTURERS and ASSISTANT LECTURERS (with a good honours degree in physiology, biochemistry or related subjects, or with medical qualifications registrable in the United Kingdom) IN THE DEPARTMENT OF PHYSIOLOGY—The Registrar, The University, Manchester, 13 (April 15).

ASSISTANT LIBRARIAN (Grade II) (with a good honours degree and preferably professional qualifications and appropriate experience)—The Registrar, The University, Liverpool, quoting Ref. CV/494 (April 16).

SENIOR LECTURER IN MATHEMATICS for duties involving lecturing on pure mathematics including, if the lecturer is so qualified, lecturing in analysis or topology—The Secretary, The University, Aberdeen (April 16).

UNIVERSITY LECTURER or UNIVERSITY DEMONSTRATOR IN THE DEPARTMENT OF PHARMACOLOGY—T. D. Kellaway, Department of Pathology, University of Cambridge, Tennis Court Road, Cambridge (April 16).

UNIVERSITY LECTURER (with at least a good honours degree in botany or agricultural botany, experience in teaching and research, and preferably with interests in, and experience of, genetics in relation to crop plant evolution) IN AGRICULTURAL BOTANY—The Secretary, School of Agriculture, University of Cambridge, Downing Street, Cambridge (April 16).

LECTURER or ASSISTANT LECTURER IN GEOLOGY at the University of the West Indies—The Inter-University Council, 33 Bedford Place, London, W.C.1 (April 18).

LECTURER or ASSISTANT LECTURER (with qualifications or interests in either climate and meteorology or the geography of planning) IN GEOGRAPHY—The Secretary, Birkbeck College (University of London), Malet Street, London, W.C.1 (April 18).

LECTURER (preferably with a good honours degree in mathematics or statistics, with further academic qualifications in mathematical statistics and/or practical experience in the use of statistical theory) IN MATHEMATICAL STATISTICS, and an ASSISTANT LECTURER (preferably with a good honours degree in mathematics or pure mathematics with further academic experience in pure mathematics, particularly in the field of algebra) IN PURE MATHEMATICS—The Secretary, University of Exeter, Northcote House, The Queen's Drive, Exeter, Devonshire (April 18).

EXPERIMENTAL OFFICER or SENIOR EXPERIMENTAL OFFICER (with a university degree or H.N.C. and preferably previous experience of electron microscopy) IN THE ELECTRON MICROSCOPE LABORATORY OF THE RHEUMATISM RESEARCH CENTRE IN THE FACULTY OF MEDICINE, to take part in an experimental programme of research in a rapidly developing branch of molecular biology—The Registrar, The University, Manchester, 13, quoting Ref. 56/66 (April 20)

ASSISTANT LECTURER IN ZOOLOGY—The Secretary, Birkbeck College (University of London), Malet Street, London, W.C.1 (April 22).

ASSISTANT LECTURER or TEMPORARY ASSISTANT LECTURER in History and Philosophy of Science—The Secretary, The Queen's University, Belfast, Northern Ireland (April 22).

DEMONSTRATORS (with a good honours degree and approximately one year's research experience) IN PHYSICAL, ORGANIC OR INORGANIC CHEMISTRY—The Registrar, University College of Wales, Aberystwyth (April 22).

LECTURER (preferably with a research interest in numerical analysis, astrophysics, or fluid dynamics) IN APPLIED MATHEMATICS—The Registrar, King's College (University of London), Strand, London, W.C.2 (April 22).

ASTOR RESEARCH FELLOW IN ENGINEERING SCIENCE—The Warden, New College, Oxford (April 23).

CHAIR OF PHYSICAL METALLURGY—The Registrar, The University, Liverpool, quoting Ref. No. RV/485 (April 23).

DEMONSTRATOR/SENIOR DEMONSTRATOR in Inorganic Chemistry—The Registrar, The University, Newcastle upon Tyne, 2 (April 23).

ASSISTANT LECTURER IN STATISTICS (preferably in mathematical statistics or probability theory)—The Registrar, The University, Hull (April 25).

JUNIOR LECTURER IN ORGANIC CHEMISTRY—The Secretary, Trinity College (University of Dublin), Dublin, 2, Republic of Ireland (April 25).

SENIOR LECTURERS (2) and a LECTURER IN THE DEPARTMENT OF PHYSICS, University of Ibadan, Nigeria—The Inter-University Council, 33 Bedford Place, London, W.C.1 (April 27).

LECTURER (with a good honours degree in geography and either a higher degree or actively engaged in research leading to a higher degree) IN GEOGRAPHY at the University of Queensland, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (London and Brisbane, April 29)

READER IN CRYSTALLOGRAPHY (Chemistry Department) at Queen Mary College—The Academic Registrar, University of London, Senate House, London, W.C.1 (April 29).

UNIVERSITY LECTURER or ASSISTANT LECTURER IN ANIMAL NUTRITION in the School of Agriculture—The Secretary, The University, Aberdeen (April 29).

ASSISTANT LECTURER or LECTURER IN CHEMISTRY (the appointment may be made in any branch of organic chemistry)—The Registrar, The University, Sheffield (April 30).

BIOLOGIST (with mechanical ability) to work on fungus pathogens of crops, especially foliage diseases in controlled environments—The Secretary, Rothamsted Experimental Station, Harpenden, Herts, quoting Ref. 1052/84 (April 30).

CHAIR OF MECHANICAL ENGINEERING—The Registrar, The University, Sheffield (April 30).

LECTURER (honours graduate with a keen research interest in the field of automatic control, and interests in the theoretical or experimental aspects of modern control techniques) IN CONTROL ENGINEERING IN THE SCHOOL OF ENGINEERING SCIENCE—The Registrar, University College of North Wales, Bangor, North Wales (April 30).

LECTURER (man or woman) IN ORGANIC CHEMISTRY—The Registrar, University College of North Wales, Bangor, North Wales (April 30).

LECTURER or ASSISTANT LECTURER IN BIOLOGICAL CHEMISTRY—The Registrar, The University, Manchester, 13, quoting Ref. 71/66 (April 30).

LECTURERS or ASSISTANT LECTURERS (2) IN THE DEPARTMENT OF CHEMISTRY, one Inorganic and one Organic—The Secretary, Sir John Cass College, Jewry Street, London, E.C.3 (April 30).

PROFESSOR OF GEOLOGY at Rhodes University, Grahamstown, South Africa—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (South Africa and London, April 30).

PROFESSOR OF PLANT PHYSIOLOGY (Rice Breeding); an ASSOCIATE PROFESSOR or SENIOR LECTURER IN AGRONOMY (Oil Palm Research); an ASSOCIATE PROFESSOR or SENIOR LECTURER IN AGRONOMY/STATISTICS; a FARM DIRECTOR (Senior Lecturer or Lecturer Level); a SENIOR LECTURER or LECTURER IN AGRICULTURAL ECONOMICS (2 posts); a SENIOR LECTURER or LECTURER IN AGRICULTURAL ENGINEERING; a SENIOR LECTURER or LECTURER IN AGRICULTURAL EXTENSION; a SENIOR LECTURER or LECTURER IN ANIMAL SCIENCE (2 posts); a SENIOR LECTURER or LECTURER IN PLANT PATHOLOGY; a SENIOR LECTURER IN SOIL CHEMISTRY; LECTURERS IN BOTANY (2 posts); LECTURERS IN GEOGRAPHY (2 posts); and a LECTURER and an ASSISTANT LECTURER/RESEARCH ASSISTANT IN ZOOLOGY, at Njala University College, Sierra Leone—The Inter-University Council, 33 Bedford Place, London, W.C.1 (April 30).

SCIENTIFIC OFFICER (with a good honours degree in biology or in chemistry, and preferably with research experience in microbiology or

biochemistry) for general studies in microbial chemistry or on the ecology of micro-organisms inoculated into soil—The Secretary, Rothamsted Experimental Station, Harpenden, Herts, quoting Ref. 1051/67 (April 30).

UNIVERSITY DEMONSTRATOR (with a good honours degree in botany and a strong interest in cytology and genetics) IN BOTANY—Dr. S Smith, Department of Zoology, University of Cambridge, Downing Street, Cambridge (April 30).

ASSISTANT LECTURER (with special interests in inorganic chemistry) IN THE DEPARTMENT OF CHEMISTRY—The Secretary, University of Exeter, Northcote House, The Queen's Drive, Exeter, Devonshire (May 1).

LECTURER (preferably with a special interest or experience in the field of small groups, or criminology, or social administration) IN SOCIOLOGY at Victoria University of Wellington, New Zealand—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (New Zealand and London, May 2).

CHAIR OF MATHEMATICAL STATISTICS at the University of Western Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, May 7).

TEACHING FELLOWS (with a Ph D) IN THE DEPARTMENT OF INORGANIC AND STRUCTURAL CHEMISTRY—The Registrar, The University, Leeds, 2 (May 7).

ASSISTANT OR ASSOCIATE PROFESSOR in one of the following fields: plant biochemistry, morphogenesis, plant ecology and biophysics—Dr. G. H. N. Towers, Head of the Department of Botany, University of British Columbia, Vancouver, 8, Canada.

ASSOCIATE PROFESSOR IN PHILOSOPHY—Head, Department of Philosophy, Queen's University, Kingston, Ontario, Canada.

ASSOCIATE PROFESSOR OF SOCIOLOGY, and ASSISTANT and ASSOCIATE PROFESSORS OF GEOGRAPHY—The President, Lakehead University, Port Arthur, Ontario, Canada.

BIOCHEMIST (with at least a good honours degree) to study problems connected with the enzyme activity and metabolism of healthy and virus-infected leaves—The Secretary, Rothamsted Experimental Station, Harpenden, Herts, quoting Ref 1051/68.

CLIMATOLOGIST to assist with an expanding programme in microclimatology, bioclimatology and comparative climatology—Prof. B. J. Garnier, Department of Geography, McGill University, Montreal, P.Q., Canada.

HEAD OF THE MATHEMATICS DEPARTMENT—The Headmaster, Queen Elizabeth Grammar School, Wakefield, Yorks.

LECTURER IN WELDING TECHNOLOGY, and a LECTURER IN GENERAL METALLURGY—The Registrar, University of Strathclyde, George Street, Glasgow, C 1.

LECTURER OR ASSISTANT LECTURER IN SOCIOLOGY with special reference to criminology and contemporary sociological theory—The Secretary and Registrar, Bristol College of Science and Technology, Ashley Down, Bristol, 7, quoting Ref. CST 66/31.

POSTDOCTORAL FELLOW IN ORGANIC CHEMISTRY to join a team working on a major synthetic project—The Registrar, The University, Manchester, 13.

RESEARCH AND DEVELOPMENT OFFICER (with an honours degree in chemistry or one of the biological sciences and preferably some research experience on cereals) for duties which will involve liaison with Universities, Research Institutes, Trade Associations and cereal growers—The Establishment Officer (R. and D. Post), Home-Grown Cereals Authority, Ingram House, 13–15 John Adam Street, London, W.C.2.

RESEARCH OFFICER (graduate) for supervisory duties in the laboratories of the DEPARTMENT OF BIOCHEMISTRY AND AGRICULTURAL BIOCHEMISTRY—The Registrar, University College of Wales, Aberystwyth.

SECOND CHAIR OF CHEMISTRY—The Academic Registrar, Northampton College of Advanced Technology, St. John Street, London, E.C.1.

REPORTS and other PUBLICATIONS

(not included in the monthly Books Supplement)

Great Britain and Ireland

Ministry of Agriculture, Fisheries and Food. Fishery Investigations, Series II, Vol. XXIV, No. 2: The Determination of Natural Mortality and Its Causes in an Exploited Population of Cockles (*Cardium edule* L.) By D. A. Hancock and A. E Urquhart. Pp. iii+40+12 plates. (London: H.M Stationery Office, 1965.) 21*s* net. [271

Geological Survey and Museum. Summary of Progress of the Geological Survey of Great Britain and the Museum of Practical Geology for the year 1964—With Report of the Geological Survey Board. Pp. vi+117+9 plates. (London: H M. Stationery Office. 1965.) 13*s*. 6*d* net. [281

The Medical Research Council of Ireland. Annual Report for the year ended December 31, 1964. Pp. v+68. (Dublin: The Medical Research Council of Ireland, 1965.) 5*s* [281

Society for the Promotion of Nature Reserves. Handbook 1965—Forty-Eighth Annual Report. Pp. 96. (London: The Society for the Promotion of Nature Reserves, British Museum (Natural History), 1966.) 12*s*. 6*d*. [281

Ministry of Technology. National Physical Laboratory. Changing to the Metric System. Conversion Factors, Symbols and Definitions By Pamela Anderton and P. H. Bigg. Pp 46. (London: H.M. Stationery Office, 1965.) 3*s*. 6*d*. net [281

Bulletin of the British Museum (Natural History). Geology Vol. 11, No. 5: Some New British Albian Ostracoda. By P. Kaye. Pp. 215–253+11 plates. (London: British Museum (Natural History), 1965) 50*s*. [281

Spectrochemical Abstracts, Vol 10, 1963–64. By Ernest H. S. van Someren, F. Lachman and F. T. Birks. Pp. 109. (London: Hilger and Watts, 1965.) 63*s*. [281

The Library Association Pamphlet No. 25: Women and Librarianship: An Investigation into certain Problems of Library Staffing By Patricia Layzell Ward. Pp. 60. (London: The Library Association, 1966.) 14*s*. (L. A members 10*s*. 6*d*.) [281

Amgueddfa Genedlaethol Cymru—National Museum of Wales. Fifty-Eighth Annual Report 1964–65. Pp. 91+4 plates. (Cardiff. National Museum of Wales, 1965.) [281

Rowett Research Institute. Annual Report on Animal Nutrition and Allied Sciences, Vol. 21, 1965. Pp 83. (Bucksburn, Aberdeen: Rowett Research Institute, 1966) 10*s*; 1.60 dollars. [281

Northern Ireland: Ministry of Agriculture. Leaflet No. 99: Cabbage and Kale for Stock Feeding. Pp. 8. (Belfast: Ministry of Agriculture, 1965.) [281

Ministry of Agriculture, Fisheries and Food. Fishery Investigations, Series II, Vol. XXIV, No 3: Whiting of the Irish Sea and the Clyde. By D. J. Garrod and R. Gambell. Pp. iv+64. (London: H.M. Stationery Office, 1965.) 20*s*. net. [281

City of Leicester Museums and Art Gallery. 59th Report, April 1st, 1964—March 31st, 1965. Pp. 48+4 plates. (Leicester: City of Leicester Museums and Art Gallery, 1965.) [281

SHIPS AND STRING AND SEALING-WAX

FOR most of the 'sixties, British industry has been dressed in sackcloth and ashes. One after another, important sectors of the British industrial economy have been examined in great detail by committees of all kinds. Most often, the reports of these proceedings have been sombre to read. Traditional and modern industries appear to have been equally open to criticism. The textile industry has taken a severe drubbing for several years, and is now undergoing yet another structural re-organization. Machine tools have been under constant fire. A few months ago the aircraft industry was closely, though unconvincingly, dissected by the Plowden Committee (*Nature*, 209, 1053; 1966). Less formally, the British computer industry is being kept under constant surveillance, though it is too soon to know whether the attempts of the British Government to concentrate development and manufacture will be successful or even well conceived. Two themes run through this spate of patient analysis. The structure of major industries is often unsuited to modern needs, commercial and otherwise. Then there is not enough research and development, and what there is tends to be used ineffectually. It is no wonder that the impression has grown up that British industry is falling quickly into decline. This is why it is such a great surprise that the report of the Geddes Committee on the British shipbuilding industry (Cmnd. 2937, H.M.S.O., 13*s*.) has turned out to be a cheerful and optimistic document.

This does not, of course, imply that all is well. By itself, the analysis of the Geddes Committee has much in common with recent tales of woe from other sectors of British industry. Products are technically sound, and sometimes excellent, but prices are often uncompetitive and delivery dates too long. This is why British shipyards are only just able to fill vacant slipways with new orders, and why the volume of production has been a diminishing proportion of the international market for ships. Relationships between shipbuilders and the suppliers on whom they rely, particularly the engine makers, are too diffuse, and complacent. The Geddes Committee hopes that reconstruction will somehow cure most of these ills. By gentle persuasion, and with the modest temptation of small supply of Government money, it hopes that the industry will coalesce into more effective units. So will British taxpayers. The Committee also hopes that the shipbuilding industry can somehow be persuaded to link its future with the steadily growing international demand for ships, and not simply to extrapolate into the future the depressing record of the past few years. The first signs are that shipbuilders are less optimistic, but—so infectious is the optimism of Geddes—they may yet be won round to believing that the future is worth having. The hallmark of the Geddes Report is the belief that the problems which have been so well identified can also, in due course, be solved. It will be interesting to see whether this is half the battle.

Meanwhile, this public scrutiny raises all the questions of how to determine what place some particular industry should have in the industrial economy of a nation, and how best science and technology may be harnessed to its ends. No amount of research and development could, by itself, make up for inadequate links between shipbuilders and those who supply them with steel or engines, for inexpert selling, bad labour relations and the lack of industrial training. It is particularly ironical that the Report should have been followed so quickly by a general increase of 4 per cent in the price of British steel. The Geddes committee was clearly surprised that, since the Second World War, one of the largest users of steel should have failed to negotiate a special price for a raw material which accounts for roughly a fifth of the price of a finished ship. Perhaps the price increasing, following so quickly on the Report, will persuade shipbuilders that their bargaining position is strong, not weak. Clearly there are limits to what science and technology can accomplish in unfavourable circumstances.

In reality, research and development in British shipbuilding are as much criticized as other parts of the industry, and rightly. Less than 1 per cent of turnover is spent on these activities, and even so, it is sometimes hard to tell where research ends and the design of particular ships begins. The co-operative research efforts which the shipbuilding industry could spare for engines were—according to Geddes—spent on steam turbines long after it had become likely that slow-speed Diesel engines were in fashion. (This does not mean that steam turbines will always languish, and there is even now a chance that slow-speed Diesels will be overtaken in performance by faster Diesels, even if shipbuilders will then have to provide more complicated reduction gearing.) Even now it is turning out to be extremely difficult for the British Government and industry to agree how best the development of competitive engines can be sponsored in partnership.

But this is only the bleak side of the picture. It is also plain that there has recently been a powerful enhancement of the industry's concern for research and of its ability to carry it out effectively. The National Physical Laboratory (which operates the most versatile model basin in Britain) is obviously hoping to find improvements of hull design for large ships as radical, and as valuable, as those which have led to the successful bulb-nosed trawler.

The study of the dynamic problems of ships at sea promises great benefits in the evolution of designs which economize in steel. Simplifying, and sometimes standardizing, the layout of ships may be well worth the study now being given to it. Automation will be increasingly used in working ships, especially as crews become more expensive. Systems for assembling steel plate are being blessed with some of the objective study they need, chiefly by the co-operative research associations for welding and shipbuilding. Hopes are running higher than for a decade. Problems abound—and Geddes asks for more money to solve them. Hopes of a flood of technical innovations are higher than for a decade.

How has all this come about? The most striking lesson to be learned from the Geddes Report is the great value of public discussion. The report on shipbuilding research in 1962 by the old Department of Scientific and Industrial Research (now merged in the Ministry of Technology) seems to have been particularly effective in giving the industry a grasp of the problem of designing modern engines. The sense of indignity engendered by a critical report can evidently work where common sense may fail. It is also plain how much can be done to revivify an industry by encouraging co-operative research financed chiefly by industry, but with backing from the Government. In British shipbuilding, the better spirit in the research associations is, so far, the most tangible sign that things may yet go well. The British Government, which has in the past tended to scorn the research associations it originally helped to create, ought to read with great care the passages in the Geddes Report on co-operative research.

TEACHING FOR EXPORT

MUCH good will come from the institution which the United Kingdom Ministry of Overseas Development and the Nuffield Foundation have chosen to call by the delicious name of CREDO ("Centre for Educational Development Overseas"). The intention is to provide a headquarters (in London) from which the use of new teaching materials developed in Britain and similar countries can be fostered in nations overseas. Inevitably, the first customers will be the nations known as underdeveloped, though it is only proper to remember that, in education, all nations are in some sense underdeveloped CREDO will work with materials and methods in all specialities, from English language to physics, though the greatest demand is likely to be for parts of the school curriculum in science. With luck, the institution should survive the three years covered by the first allocation of funds—especially if by then the Ministry of Overseas Development has the funds to sustain the good works it is always talking about.

The need for a mechanism for channelling educational aid to nations overseas should not, of course, obscure the difficulties of these operations. For one thing, it is necessary to avoid suspicions of neo-colonialism. Especially in dealings with African nations, CREDO will have to tread warily. It is understandable that many nations should fear that the old slogan about trade following the flag has now been replaced by a link between education and political influence. The sponsors of CREDO are mercifully seized of this danger. They seem also to acknowledge the difficulties of transplanting educational methods and materials from one environment to some other. The difficulty is that a sensitively designed curriculum is an intellectual and social entity in which should ideally participate whole communities of teachers. It follows that the best way to export teaching is to enable nations wishing to improve themselves to study, mimic and adapt those parts of practice elsewhere that seem to be desirable. By this test, CREDO will be most successful if it can avoid thinking of itself as an export agency; the ideal is that it should assist developing nations to create for themselves machinery by which curriculum development can be begun and then sustained.

IDEAS AND WORDS

Scientific Psychology

Principles and Approaches. Edited by Benjamin B. Wolman and Ernest Nagel. Pp. xv+620. (New York and London: Basic Books, 1965.) 70*s*.

ONCE upon a time philosophy gave birth to a large family of sciences. One by one they broke away from the maternal apron-strings. For psychology, however, the youngest of these, the breakaway proved a mixed blessing. No sooner did she walk alone than she found her footsteps dogged by seducers: behaviourism, reductionism, positivism, and a host of others.

In the face of these perils, and on the initiative of Dr. B. B. Wolman, the editor of *Scientific Psychology*, thirty scholars have been mobilized to advise on the defensive measures to be taken. At the outset, his co-editor, Ernest Nagel, counsels a return to the security of mother philosophy.

Dr. Wolman hopes that the compendium will establish a science of science, defined as the study, by scientific methods, of "systems of propositions which convey a certain kind of knowledge". This task he considers to be different from the psychology, sociology or history of science. Prof. Arne Naess takes up his challenge to create a metascience, and gives us a lively critique of the idea that scientists, in the course of their work, can be studied as if they were rats in mazes. For, he remarks, unlike the psychologist who himself constructs the mazes into which the rats are placed, the metascientist may have no idea of the 'maze' in which his 'rat' finds itself. That is, he may know little of the problems, goals, culs-de-sac or rewards of the scientist. Prof. Naess concludes that the metascientist cannot observe science from the outside. He must somehow participate in the labours of those who constitute his subject-matter. This participation is of special significance to psychologists because they have a similar relationship to their subject-matter, human beings.

Other contributors are concerned with philosophical or logical aspects of psychological issues. Outstanding among these are Jean Piaget and J.-B. Grize, who discuss the basis of genetic epistemology. This is a branch of psychology which traces, stage by stage, the natural development in the individual child of those mental operations which eventually come to grips with the essential concepts of mathematics and physical science. Piaget turns the tables on the editors by suggesting that a sound philosophy must rest on empirical psychology, rather than vice versa, for the concepts of mathematics and physics do not spring ready-made from the mind, nor are they abstracted from the objects of observation. They always presuppose a series of interactions between the thinking subject and the object of his thought. The study of child development thus poses questions which converge with the great problems of epistemology and the philosophy of the sciences: How is logic related to language? What is causality? Is number an intuitive concept? How is the idea of speed related to that of time? And so on.

Most of the contributors either limit themselves to philosophical problems as such or to particular psychological systems. Among the former are G. J. Warnock, who writes on logical analysis and the nature of thought, and D. M. Armstrong, who expounds a theory of perception. The latter are excessively represented by theorists of learning, including an admirable chapter by B. F. Ritchie, who is troubled about the vagueness of learning theory. Prof. Ritchie proposes two axioms for metascience. One relates to the scientist whose confidence in his theory is directly proportionate to the degree to which he cherishes it. The other applies to the scientist who on discovering a fact which contradicts his theory, revises his theory to render it untestable.

The chapters vary in quality. Some are written in an obscure prose exemplified by the title of the editor's final

chapter, "Principles of Monistic Transitionism", designed presumably to bring some unity to an otherwise loose ensemble.

JOHN COHEN

EVOLVING THE RULES OF WORKING TOGETHER

Industrial Relations in Engineering

By Arthur Marsh. (The Commonwealth and International Library of Science, Technology, Engineering and Liberal Studies.) Pp. xxiii+362. (London and New York: Pergamon Press, Ltd., 1965.) 30*s*. net.

IN the words of the author, the purpose of *Industrial Relations in Engineering* is to examine the present-day workings of industrial relations and to encourage trade unionists, managers and students of industrial relations to discuss the strength and weaknesses of the system.

The rate and pressure of technical change, particularly automation, which is likely to affect the jobs of many people, the need for a critical look at craft apprenticeships and retraining within industry and the impact of national planning, are all factors which stimulate interest and direct attention to what is undoubtedly the most important factor in the evolution of modern industrial life.

It would not be untrue to say that 'industrial relations' is, when brought down to factory level, where all negotiations begin, but another term for 'personnel management', the emphasis being placed on the aspect of employee relationship rather than executive policies and activities that are set up to foster good relations. Both are clearly allied to morale and good morale makes for effective work and economical operation.

Arthur Marsh in his study has drawn on his wide knowledge gained while developing extra-mural classes for industry at the University of Oxford, and quite logically his opening chapters deal with the historical background of trade unionism, the problem of defining engineering and the slow but steady emergence of Union organization and negotiation procedures from the early local committees to a national body in the form of a federation which is described in the Trades Union Congress Report (1947) as "a loose form of industrial unionism" and is a compromise between *ad hoc* working arrangements and a complete amalgamation of associated bodies.

In this role, the Confederation of Shipbuilding and Engineering Unions (C.S.E.U.) serves a very good purpose and prevents inter-union competition and overlapping.

The next chapter summarizes the general position and function of the C.S.E.U. and is followed by a description of the nature and origin of the managerial side of industrial relations. The role of the Engineering Employers' Federation, expressed in the simplest possible terms, is that it acts as the trade union for management.

The chapter dealing with the history and operation of the Engineering Employers' Federation is one of great interest, as it explains very clearly the reason for the defensive role undertaken in labour relations and why the local association structure of the organization has survived and continues. The comments of the author on the future of the Federation could be the subject for much comment and debate, but it is Chapter 8—"The Engineering System in Perspective"—which discusses the reaction of those inside and outside the industry to the many features in the Unions' and Federation's handling of disputes which is most important and gives scope for criticism and an urge to reorganize. The final paragraph of the chapter which deals with the influence exerted on industry by Government could quite easily have been considerably extended and perhaps in time this aspect of the subject will merit a volume to itself. The author mentions the Industrial Training Act, which is just beginning to bite and has received a mixed reception from employers but so far little published reaction from Unions.

The activities of the National Board for Prices and Incomes and the effect of restraint on prices without effective control of wages indicate that more Government pressure is essential if its policies are to be effective. Government influence is becoming a third factor in industrial relations, as since 1945 and especially since 1961 both Conservative and Labour Governments have found it necessary to intervene more directly in the affairs of industrial relations.

The latter part of the book is taken up with appendixes A to D, and these give much valuable information on the main negotiating bodies, procedures and agreements from the year 1898 to the 'packaged deal agreement' of December 22, 1964, and in a section labelled "Miscellaneous" there are notes on apprentice indentures, training of shop stewards, collective bargaining and procedures for dealing with redundancy.

There are all too few books written on industrial relations. This subject should be more widely known, understood and discussed: Arthur Marsh's book, although written primarily to advance teaching to a selected readership, can be of great interest to a broader section of the community—those who, while having no part in the engineering industry, are nevertheless affected by industrial disunity.

The arrangement of chapters and the details given in each will enable a reader to build up, step by step, a picture of the complex negotiating machinery and the code of behaviour evolved over a period of one hundred and fifty years of industrial growth to give Britain her present organization and procedure.

In this book we have all the history, the rules of the game, and an introduction to the characters and organization, and in studying it a reader can form his own opinion of a relationship which can affect us all, our work, our money, and our security and future.

L. E. JARMAN

INTRODUCTION TO NEUTRON RADIOGRAPHY

Neutron Radiography

Methods, Capabilities and Applications. By Harold Berger. Pp. vi+146. (Amsterdam, London and New York: Elsevier Publishing Company, 1965.) 50*s*.

HAROLD BERGER has produced an authoritative and clearly expressed book which provides an excellent survey of neutron radiography for the non-specialist reader and a thoroughly worth-while reference book for the worker in this comparatively new field. The value of *Neutron Radiography* to the specialist is considerably enhanced by a comprehensive and up-to-date bibliography.

After an introductory chapter in which the role of neutron radiography as complementary to X- and γ-radiography is reviewed, the author discusses the use of accelerators, radioactive sources and reactors as sources of neutrons for slow neutron radiography. Emphasis is placed on the use of reactors because of the higher fluxes available, and here the author could possibly be criticized for underestimating the potential use of low-energy accelerators which have the advantage of cheapness and mobility and which are gradually being developed to produce higher neutron yields. The comment has perhaps more relevance to the potential user in Britain where research reactors are less readily accessible to industrial research teams.

An excellent chapter deals with photographic methods for neutron detection, and here Harold Berger demonstrates to the full his ability to write for the specialist and non-specialist reader. His somewhat superficial treatment

of the nuclear processes involved may slightly irritate the nuclear physicist, yet they perform the essential function of providing the necessary background information to enable the non-specialist to understand and appreciate an excellent exposition of the practical techniques and relative merits of direct and transfer exposure methods. In a more speculative chapter dealing with non-photographic methods of neutron detection, the author concludes that neutron image intensifiers and multiwire spark counters are likely to be of future interest.

Practical considerations such as shutter design, the effect of collimation on resolution and the resolution, contrast and speed obtainable with various converter screen combinations using direct and transfer exposure techniques are discussed in Chapter 6, in sufficient detail to satisfy the potential user, while the following chapter on capabilities and limitations of the technique will be of more general interest. A chapter on applications is slightly biased towards applications in the reactor field, but here and elsewhere applications in metallurgy, biology and solid-state physics are adequately covered. Numerous excellent reproductions of neutron radiographs occur throughout the text.

Although clearly an enthusiast, Harold Berger is to be congratulated in preserving a well-balanced and objective point of view throughout, neither over- nor under-estimating the potential usefulness of this developing technique.

S. E. HUNT

RADIOACTIVITY OF THE HEAVY ELEMENTS

The Nuclear Properties of the Heavy Elements

By E. K. Hyde, I. Perlman and G. T. Seaborg. Vol. 1: Systematics of Nuclear Structure and Radioactivity. Pp. xv+406+xvii. 120*s*. Vol. 2: Detailed Radioactive Properties. Pp. xvi+407–1107+xlix. 200*s*. Vol. 3: Fission Phenomena. By E. K. Hyde. Pp. xvii+519+xxiv. 144*s*. (Englewood Cliffs, N.J., and London: Prentice Hall International, 1964.)

BEYOND thallium, alpha decay becomes an important factor determining the nuclear stability of the isotopes of each element. The twenty-two elements at present comprising this class are commonly called the heavy elements. Half are synthetic species; the remainder occur in the three natural radioactive decay series, although two of them only arise from minor decay modes. Three stable nuclides, isotopes of lead, are included, along with some three hundred radioactive nuclides and about twenty nuclear isomers of appreciable lifetime. Except for the forty-eight naturally occurring species, the investigation of which has been pursued in France since the early discoveries in radioactivity, the experimental exploration of this field has taken place predominantly in the United States. No one laboratory has a more distinguished record in the field than the E. O. Lawrence Radiation Laboratory in the University of California, Berkeley. This Laboratory was associated with the discovery of all the eleven synthetic elements.

Some of the wisdom and experience of this Laboratory has now been condensed into three volumes, jointly entitled *The Nuclear Properties of the Heavy Elements*. The first volume deals with the semi-empirical theoretical analysis of the nuclear data with which the Berkeley school has been so successful. The first two chapters provide the basic experimental data, the masses and nucleon separation energies and decay energy cycles linking all the known species. Problems arising in the selection of a compatible set of data are considered. The major portion of this volume is devoted to an account of the single independent particle and the unified models of the nucleus and their application to the interpretation of the large body of experimental data on decay processes and the excited states of these nuclei. This is followed by a detailed consideration of the alpha decay processes, their spectra and kinetics and interpretation in terms of hindrance factors. The fifth and final chapter deals with quite a different theme, the production of the synthetic heavy element nuclides. Each of the principal methods, bombardment with protons, deuterons or helium nuclei of moderate energy, bombardment with high-energy heavier nuclei and repeated neutron capture, is discussed in detail. The chapter finishes with a very brief account of cosmic nucleogenetic processes. Appendixes tabulate the electron binding and characteristic X-ray energies in these elements, Auger electron energies and fluorescent yields.

A noteworthy feature of this volume is the minimum of mathematical detail included in the portions dealing with nuclear models and the kinetics of alpha decay. Where appropriate, reference is made to earlier work of historical significance; for example, the pioneering work of Schintlmeister in this field is acknowledged.

The second volume contains a comprehensive account of the three hundred or more nuclides of these elements so far examined. For each nuclide treated the data recorded include the history of its discovery and first mode of preparation, the best alternative modes of preparation, a complete account of its properties, saving only fission properties which are reserved for the third volume, and the interpretation of these properties in terms of the shell and/or unified nuclear models.

The sequence chosen is at first a little unusual. The natural decay series and their members are treated first. This chapter contains a good deal of historical material and includes some topics, such as a brief account of assay methods for radium, that are not considered for the remaining species. There is also a substantial digression on nuclear geochronological procedures following the stable isotopes of lead.

Next, the six synthetic collateral decay series and the two $4n + 1$ series are considered. At the end of this chapter a very useful collection of reference alpha spectra of the members of both the natural and synthetic decay series appears. The isotopes of thorium, protactinium and uranium are then treated in order of mass number followed by a similar treatment, element by element, of the transuranium species. This final chapter, indeed, comprises about one-third of this volume. It describes the lighter isotopes of the natural elements not included in the previous chapters together with a good deal of discussion of the special features of these nearly spherical nuclei lying on a relatively flat part of the mass energy surface below the 126 neutron shell.

This grouping of the material inevitably leads to some measure of duplication and this is enhanced by an attempt to make each volume reasonably self-contained. Besides the subject and author indexes included in Volume 1, Volume 2 closes with similar cumulative indexes; in addition, it includes an isotopic index. The two volumes form a natural unit and indeed the pages in Volume 2 are numbered to follow those of Volume 1. The enormous volume of quantitative data contained is generally clearly presented and extensive use is made of graphical, tabular and other diagrammatic forms of presentation. Together, the two volumes contain more than two thousand references to original material. Many of these relate to unpublished work or to papers that have appeared in the profusion of official documents, reports, etc., which are often less readily available than the usual academic journals. For this reason alone these volumes will be one of the key works of reference for any library serving the nuclear scientist.

The third volume covers the phenomena of fission. It is surprising, in view of the substantial literature of the subject and the appearance of a number of good reviews covering particular aspects of fission, that this is the first monograph devoted exclusively to fission. It reminds one

that, despite the rapidly developing industry based on this phenomenon, the time that has elapsed since its discovery, and the considerable body of related research published every year, there is still no satisfactory theoretical account of fission. Nor are the experimental data yet so complete that one feels that nothing can be done which will add to our picture of the process.

This volume is divided into two parts. The first deals with low-energy fission, treating in succession the history, theory, cross-sections; mass, charge and kinetic energy distributions of the fission fragments; the characteristics of the prompt and delayed neutrons and the prompt gamma radiation. The second part deals with the more energetic fission processes, first in the region where compound nucleus formation is still important. A critical account is given of the substantial body of data on mass yield curves for these processes. A description of the high-energy fission processes follows, the results being interpreted in terms of the Serber model. A brief chapter on meson fission and a more extensive one on photo-fission complete the book. This volume is clearly the most comprehensive, authoritative and scholarly work on the fission process.

All three authors are experienced writers and the text generally reads very agreeably. As no doubt the price indicates, these volumes are well bound and produced. It is virtually impossible to avoid some typographical errors in such complex productions, but these are very few and far between. Taken together, the three volumes are a remarkable and invaluable contribution to nuclear science and will be essential volumes to all libraries covering this field.

A. G. MADDOCK

SOME ASPECTS OF MICROCIRCULATORY STUDIES

Microhemocirculation

Observable Variables and Their Biologic Control. By Prof. Elio Maggio. Pp. xiii+194. (Springfield, Ill.: Charles C. Thomas, 1965.) 16.50 dollars.

MICROHEMOCIRCULATION is, in revised form, the English publication of Prof. Maggio's work, *Micro-e-macro-emocircolazione*, published in Italy in 1962. According to the author, the script is designed for scientists interested in biology, teachers and students in medical schools, and physicians wishing to correlate clinical symptoms and signs with the results of experimental studies of microvascular problems.

Essentially the book is in six parts: (1) a historical survey of important macro- and micro-circulatory discoveries from the Hellenistic period to the present day; (2) methods of investigating the microcirculation; (3) a section consisting of two chapters devoted to a description of the distribution and structure of microvascular beds, their haemodynamics, transcapillary exchange and the chemical and nervous factors which may influence the size of microvessels; (4) the reaction of microvessels to pathological circumstances; (5) the response of vessels to tissue injury; (6) a short atlas of plates showing microvessels under normal conditions and their reactions to trauma and infection.

At a time when the emphasis on various parts of the medical curriculum is under review and the tendency is for reasonably abbreviated text-books to be prescribed, the place of any book, in the armament of the average student, which deals entirely with microcirculatory problems must be questioned. Nevertheless, the author must be congratulated in attempting to bridge the traditional schisms of teaching by considering the normal structure, function and pathology of microvessels in such short space. As a result, however, much is omitted and it is for this reason that the use of this book is largely extra-curricular, perhaps appealing to an undergraduate student wishing background reading during the preparation of a thesis, or providing a rapid synopsis of available methods for investigating some aspect of the microcirculation.

The historical survey is short but adequate, lucidly depicting the evolution of facts concerning the circulation and their separation from the various hypotheses of earlier centuries. The chapter dealing with methods of investigation serves only as an introduction to available techniques, no single method being considered in detail. Regrettably, when referring to histological techniques for validating observations made *in vivo*, the author fails to mention any but his own particular method, thus giving an unbalanced effect to the general discussion.

When considering the normal structure and distribution of capillary beds, the subject is considered so briefly that little information would be imparted to a student with little previous knowledge, the only microcirculation being described in any detail being that of the placenta. On p. 61 capillaries are defined, without qualification, as having a diameter of 2–18μ and are mentioned synonymously with sinusoids. These and other points would mislead the medical student who, in Britain, is concerned primarily with human anatomy. The present views on the control of microvessels by chemical mediators is rapidly reviewed, but the discussion of the part played by the nervous system is inadequate, presupposing considerable knowledge of neuroanatomy.

Two concluding chapters, very briefly, describe the elementary facts concerning responses of microvessels to inflammation, the role of mast cells and tissue response to injury. Brevity is often necessary, but it defeats its purpose here and it is impossible to give a coherent description of the mechanisms of blood coagulation in half a page and claim an adequate standard has been achieved.

An atlas of black-and-white illustrations reveals the value of various techniques in microvascular studies, the pictures of perivascular lining by mast cells, platelet adhesion to the endothelium and the formation of white thrombi in veins after experimental introduction of pathogenic organisms being impressive.

The majority of illustrations supporting the script are acknowledged from the works of other authors. Two electron micrographs (Figs. 25 and 26) are of poor quality, a better reproduction of an arterio-venous anastomosis (Fig. 24) is desirable, and Fig. 23, which shows the course of the spiral arteries and veins of the placenta, is reduced excessively. In style the publication has suffered during the translation, and phrases like "anatomo-physiologic variables of the microhaemocirculation" are a little frightening to the student. The bibliography is extensive enough to lead one into the subject deeply.

As a text on the normal structure, function and pathology of the microvessels, this book must be accounted a disappointment.

JOHN A. CLARKE

SIXTY YEARS OF TISSUE CULTURE

Cells and Tissues in Culture

Methods, Biology and Physiology. Edited by E. N. Willmer. Vol. 1: Pp. xiv+782. Vol. 2: Pp. xvi+809. (London: Academic Press, Inc. (London), Ltd.; New York: Academic Press, Inc., 1965.) 168*s*. each volume.

"TISSUE culture is humanly important only in so far as it functions as a substrate for the growth of pathogenic or potentially pathogenic viruses."

Whether or not one agrees with this statement by Sir Francis Burnet (*Lancet*, i, 37; 1966) will depend on one's involvement in tissue culture and on the interpretation given to the words "humanly important". One way of assessing its validity might be to read the two volumes of *Cells and Tissues in Culture* which the editor, Dr. E. N. Willmer, describes as "an attempt to show what

has been achieved so far and to discuss where, when and how the technique may be most profitably employed". They are intended to sum up the contributions made by tissue culture to various biological fields during the 60 years since Ross G. Harrison showed that the method was capable of solving fundamental problems; at the same time, they provide an excellent guide for anyone contemplating the application of these techniques in a particular research programme.

The first volume is concerned with general matters apropos of cells and tissues in culture, including culture methods and media, the identification of cells *in vitro*, their motility and metabolism, cell division, and the actions of hormones and vitamins on cultured cells. The second deals with the techniques appropriate to the study of specific cells and tissues, and reviews the information already derived from their use, ranging from macrophages, lymphocytes and bone marrow, via bone and tooth, through muscle, nervous tissue and the special sense organs, to the culture of exocrine and endocrine glands and the gonads, with chapters on skin and the respiratory system.

A third volume is in preparation which will contain articles on various specialized, but important, topics such as malignant cells, antibody production *in vitro*, the use of tissue culture in radiobiology and virology, and plant tissue culture.

From their primary growth in the early years of this century, tissue culture techniques have now metastasized throughout the whole body of biological research, and as Dr. Willmer has called on the services of almost fifty contributors to give adequate coverage to these widely different topics, it is impossible for one individual to give a valid judgment on each and every chapter, and comment must be limited to a sample dictated by personal interests.

The opening chapter by Moscona, Trowell and Willmer is a necessarily brief account of the routine methods of tissue, cell and organ culture with comments on their advantages and drawbacks, sufficiently informative to satisfy the curiosity of the worker in other fields or to give the tyro an overall view leading him on to the standard books on techniques. The section on problems of cell identification by Willmer is a condensation of his classic *Cytology and Evolution*, and serves its purpose as a warning of the dangers of giving too precise a name to a particular variety of cell in culture. Abercrombie's chapter on the locomotion of cells considers the factors which may influence the movement of cells on the surfaces commonly available to them *in vitro*, and illustrates the difficulties involved in any attempt to explain events occurring *in vivo* on the basis of cellular activity in the totally abnormal environment of the culture.

The contributions in Volume 1 concerned with the carbohydrate, protein and nucleic acid metabolism of cultured cells cannot be critically assessed by a non-biochemist, but are clearly essential in a work of this kind.

The chapter on genetic cytology by Hsu must be mentioned, partly because it provides an outstanding example of the ability of tissue culture techniques to clarify a previously obscure field in biology and medicine, and also because the style of this author has enviable lightness of touch which makes a most complex topic enjoyable and easy to comprehend. There is little doubt that the recent rapid advances in the understanding of chromosomal aberrations owe as much to simple cell cultures as to the higher flights of molecular biology.

The remaining topics covered in the first volume—differentiation, cell aggregates, embryogenesis, the actions of hormones and vitamins—are all dealt with expertly by leading workers in these fields of tissue culture, and exemplify the value of the method as a means of isolating tissues and controlling their environment.

The second volume opens with an account by Jacoby of the cultural characteristics of the macrophage, a cell which is perhaps happier than most in the milieu of the culture flask or chamber and which is a rewarding subject for such investigation, since it is virtually a free-living organism within the body and readily adapts itself to new surroundings. The same cannot, alas, be said of the lymphocyte, which is notoriously reluctant to respond to the blandishments of the tissue culturist, dying rapidly *in vitro* however rich and succulent the medium offered to it. Trowell, who has made greater efforts than anyone to satisfy the requirements of this *prima donna* among cells, provides a thorough review of the somewhat negative information available.

One of the most successful applications of the organ culture method (as distinct from cell or tissue culture) has been in the growth of isolated rudimentary bones, which Fell and Robison used to such good effect; Chapter 4 in the second volume, by Biggers, collates the results of experiments based on this procedure—a further example of the value of isolating a tissue or organ so that viability, growth and differentiation can continue under closely controlled conditions. This is succeeded by a short discussion on the osteoclast by Hancox, whose use of the cell culture technique contrasts well with the preceding chapter.

The nervous system was not only one of the first tissues to be examined by *in vitro* methods, but has also continued to be one of the most intensively studied, and with the steady improvement in culture techniques the point has now been reached where myelination in culture can regularly be achieved, thanks to the groundwork carried out by biologists such as Margaret Murray. She sums up the situation with regard to nervous tissues in the ninth chapter of Volume 2, dealing with, *inter alia*, the stimulation of nerve fibre growth, the differentiation of neurone cytoplasm, myelination, and the culture of neuroglia. This chapter includes a section by Crane on the electrophysiological activity present in cultured neurones and neuroglial cells, which, when considered together with the light and electron microscopic evidence, implies a surprising degree of functional and structural organization in explanted nervous tissue.

Dr. Willmer has chosen his contributors well, and they have not let him down; the Academic Press have turned out the books to their usual high standard. Criticisms can only be minor and carping—there might, for example, have been a chapter on the application of the phase, interference and fluorescence microscopes, which could usefully have included more than a mere passing reference to the preparation of cultured tissue for electron mic[illegible] scopy. It was disappointing to find that few of the auth[illegible] have used phase-contrast photomicrographs, which c[illegible] have an intrinsic beauty, in their illustrations. Refer[illegible] to clones or 'pure' strains of cells are brief and scatte[illegible] and could preferably have been brought together in a separate chapter.

Dr. Willmer has already done much to correct the once widespread impression that tissue culture is a recondite and difficult procedure of doubtful value; this most recent product of his energy and enthusiasm should finally eradicate this belief and show that, irrespective of whether it is "humanly important", it is a valid biological tool capable of achieving preparations with an aesthetic appeal as well as great scientific potential.

J. A. SHARP

AMNESIA

Deranged Memory

A Psychonomic Study of the Amnesic Syndrome. By George A. Talland. Pp. xi + 356. (New York: Academic Press, Inc.; London: Academic Press, Inc. (Lond[illegible] Ltd., 1965.) 75*s*.

IN 1887, S. S. Korsakoff, a noted Russian psychiatrist, described a number of cases in which unusual psychical symptoms were associated with severe alcoholic ne[illegible]

pathy. In his view, the central feature of the disorder was "an extraordinarily peculiar amnesia, in which the memory for recent events, those that have just happened, is principally involved, whereas the remote past is remembered fairly well". His observations were abundantly confirmed by others, though it soon became clear that this curious disorder is not exclusively linked with chronic alcoholism and may be regarded as a reaction of the brain to a wide variety of pathological agencies. It was therefore christened the Korsakoff syndrome, by which name it has since been generally known.

In view of the widespread preoccupation with the cerebral basis of memory, it is odd that the Korsakoff syndrome has not attracted greater scientific interest. For here we see a remarkable dissociation between memory, which is often most severely impaired, and other psychological functions, such as intelligence, which are little, if at all, affected. So clear-cut a dissociation cannot, so far as is known at present, be produced experimentally in animals, and may perhaps reflect a special characteristic of the human brain.

Dr. Talland presents an excellent account of the Korsakoff syndrome from the psychological point of view. He is particularly good on the historical aspect, and has made a real effort to understand the laborious German work on the subject, which at its best is extremely penetrating, though at its worst turgid and quasi-metaphysical. Indeed, *Deranged Memory* is the first really adequate digest of the literature on the Korsakoff syndrome so far to appear in English.

Included also are the results of a considerable number of controlled psychological experiments which the author has himself carried out with Korsakoff patients, some of which have already been reported elsewhere. These experiments have two aims: first, to ascertain the general psychological status of the Korsakoff patient, and secondly, to throw light on the nature of the memory defect itself. As regards the first aim, Dr. Talland shows, as have others before him, that the defect of memory is seldom absolutely circumscribed. Minor abnormalities in perception, intelligence and reasoning can often be elicited by special tests, even if clinically inapparent. As regards the second aim, Dr. Talland is able to show that the memory loss cannot be exclusively ascribed to a failure of registration, of retention or of recall. All three phases of the memory process suffer, as does also associative learning. Indeed, all that one can really conclude from these experiments is that the rate of forgetting is enormously accelerated in Korsakoff patients, such that they become virtually unable to learn or to build up a coherent record of their present experience. As Sir Aubrey Lewis has well said, the differences between the amnesic and the normal state are quantitative rather than qualitative, and involve no factors not already known from the investigation of normal memory.

It is perhaps a pity that Dr. Talland pays so little attention to the neuropathology of the Korsakoff syndrome and its relation to the more strictly circumscribed defects of memory that are now known to result from bilateral lesions in the hippocampal region of the brain. For, in these cases, one may see a relatively pure memory disorder, lacking the confabulation and disorientation so characteristic of the Korsakoff state. Indeed, the latter is unlikely to prove altogether simple, from the psychological point of view, and almost certainly involves defects in insight and judgment which are not necessarily linked with, let alone derived from, the peculiar disorder of memory. These additional defects may well derive from subcortical brain damage, which has been established in many typical cases of alcoholic Korsakoff syndrome.

This interesting and unusual book may be commended to psychologists and others with an interest in memory and its disorders, It is well organized and clearly written, and will long remain a valuable source book. Unfortunately the price is rather high.

O. L. ZANGWILL

RESPONSES OF INDIVIDUALS AND ENVIRONMENTS

Psychobiological Approaches to Social Behavior

Edited by P. H. Leiderman and D. Shapiro. Pp. xv + 203. (London : Tavistock Publications, Ltd., 1965.) 48*s*.

A SYMPOSIUM, sponsored jointly by the Department of Psychiatry of the Harvard Medical School and the U.S. Office of Naval Research, was held in 1963 to bring together individuals concerned with an increasingly significant field of psychological investigation, the impact of social and group environment on the emotional and bodily responses of man. It seems so apparent that psychological functioning must be influenced by the social environment that it is almost startling to note that the social psychological background is rarely specified in physiological investigation. *Psychobiological Approaches to Social Behavior* brings together data which would normally be spread through the literature of several disciplines. Among the interactions of the different life sciences which were described by various authors are the sensitivity of psychoendocrine systems to social and physical environment; plasma-lipid responses to leadership, conformity and deviation; muscular tension; physiological activation or psychological act ?; the interaction of the cognitive and physiological determinants of emotional state; and the experimental exploration of the et-epimeletic or care-soliciting behavioural system.

Bringing together the proceedings of this symposium for publication in book form has been entrusted to Prof. P. H. Leiderman and Prof. D. Shapiro, well known for their work showing how social factors in small group interaction influence the galvanic skin potential. In a concluding chapter they discuss the implications for future research of the investigations reported and rightly suggest that there has already been established a methodological and conceptual framework for fruitful exchange between the psychological and the social sciences. The exchange will almost certainly include a wide extension of suitable mathematical techniques. Future research should proceed from those studies which attempt to manipulate social variables by pre-experimental selection and arrangement of individuals. In the words of the editors, "small groups of two, three and four subjects could be studied under the varying effects of social approval and disapproval, success and failure, co-operation and competition, formal and informal social settings, conditions of isolation, and varying social relationships. Groups selected for personality type, patient category, occupational group, sex and ethnicity could be included in these different social environments". Other investigations could begin with the study of the socialization of physiological response levels during the course of maturation; useful information concerning individual and family structure could be obtained by physiological studies of family interaction during the course of development. Another area of research which would have an important bearing on psychosomatic medicine is the degree to which visceral responses can be learned or unlearned under different conditions of social reward. Equally, as the editors show, the relationship between pharmacological agents and social behaviour is almost unexplored. "A social situation is the only appropriate testing ground for assessing the value of a drug in influencing an individual's adaptation to his social environment." Other lines of research which are indicated from this fascinating integration of social and biological factors would stem from human evolution, genetics and ecology. The editors and authors could fairly claim that this report of their symposium is not only an important and exciting book but provides guidelines for much inter-disciplinary co-operation between workers in the psycho-biological fields of to-morrow.

T. H. HAWKINS

Mach Bands

Quantitative Studies on Neural Networks in the Retina. By Dr. Floyd Ratliff. Pp. xii+365. (San Francisco, London and Amsterdam: Holden-Day, Inc., 1965.) 15.25 dollars.

THIS interesting and unusual book contains three main portions. The first is devoted to a most fascinating biography of Ernst Mach along with a description of his major contributions in the fields of philosophy, physics and biology. Ratliff shows how these interests in diverse fields were intertwined and gives them a unity.

In the middle portion of *Mach Bands* the author lucidly describes Mach's original discovery of a most remarkable visual phenomenon—now called Mach bands. If the eye is presented with a sudden change in contrast gradient, such as occurs with the diffuse shadow of an edge, the subject perceives a bright band where the gradient is negative and a dark band where the gradient is positive. Mach could foresee that this was an important property of the visual nervous system and that it would enable the visual system to transmit information about the presence of contours. Almost a century had to pass before Ratliff and other neurophysiologists demonstrated the existence of this effect in single nerve fibres passing from the eye to the brain. Ratliff successfully attempts to integrate Mach's original psychophysical observations with our modern knowledge of neurophysiology and discusses the relevance of these findings to present-day theories of how we perceive detail.

The final portion of the book is a translation of the six relevant papers that Mach published between 1865 and 1906. In view of the present research interest in this field, these translations will form a most convenient reference source.

This book can be thoroughly recommended to all experimental psychologists and physiologists interested in the visual system, and to all those who have to use, or be aware of, some of the strange properties of the visual sense.

F. W. CAMPBELL

The Biliary System

Edited by Dr. W. Taylor. (A Symposium of the NATO Advanced Study Institute.) Pp. xxv+712. (Oxford: Blackwell Scientific Publications, 1965.) 135*s*. net.

THE Biliary System is a report of a symposium held in Newcastle in the autumn of 1963 under the auspices of the North Atlantic Treaty Organization. The conference was attended by some ninety authorities on liver function from all over the world, and a high proportion of these presented communications to the conference.

The subjects were classified in eight main divisions commencing with structural and functional relationships of the liver and including various metabolic and clinical aspects of the subject. All the contributions are well written and illustrated and each one constitutes either an important new contribution to the subject or a valuable summary of the existing situation. Most of the papers have a short summary or conclusion at the end, but it would have been an improvement if this had been insisted on in each case.

With such a variety of papers it would be invidious to select any for special mention, but I was particularly impressed with the sections on biliary secretion in man and with that on bilirubin metabolism. The unexpected difference in the intestinal absorption of conjugated and unconjugated bilirubin is specially interesting in its relation to the biological purpose of conjugation, and the problem of cholestasis is well reviewed. New information on congenital, non-haemolytic jaundice is contributed by several authors.

The work concludes with a series of short summarizing articles by Prof. Sheila Sherlock, Dr. R. W. Brauer, Prof. W. H. H. Andrews and Dr. A. E. Doisy which give a very valuable perspective of the conference and should, perhaps, be read first. The book is extremely well produced and the whole production is a tribute to the organizing powers of Dr. W. Taylor, who acted as director of the conference; it should certainly be read by all interested in any aspect of liver function and represents good value at the price.

N. F. MACLAGAN

Advances in Ecological Research

Vol. 2. Edited by J. B. Cragg. Pp. xi+264. (London: Academic Press, Inc. (London), Ltd.; New York: Academic Press, Inc., 1964.) 57*s*. 6*d*.

THIS is a continuation of a series designed to provide biologists with a balanced view of recent developments in the ecological investigation of plants and animals. The volume consists of four substantial articles. In the first, M. E. Solomon considers the processes involved in the natural control of insects and mites, placing emphasis on the results of practical studies of population dynamics, the type of data required for the study of natural control and their analysis. Under the title "The Use of Statistics in Phytosociology", Lambert and Dale deal with the problem of putting the investigation of vegetation on an objective basis by the use of appropriate statistical techniques. The third article, by Bray and Gorham, is a report of their study on litter production in forests of the world. In this they discuss the components of litter, the factors affecting litter-fall and the seasonal changes in the standing crop of leaves. They conclude with a consideration of leaf litter as an index to net production. The final and by far the largest article is by Heslop-Harrison, who reviews the development of concepts and methods in genecology during the preceding forty years.

Without exception the papers are well and attractively written and together constitute an important and stimulating contribution to the modern science of ecology.

K. JONES

Preparation and Bio-Medical Application of Labelled Molecules

Edited by J. Sirchis. (Proceedings of a Symposium sponsored by the Radiation Chemistry and Radioelements Centers of the Universities of Bologna, Padua and Rome; the Italian National Research Council; and the European Atomic Energy Community, Venice, August 23–29, 1964.) Pp. xviii+502. (Brussels: European Atomic Energy Community, 1964.) n.p.

THIS is a compendium of information on the chemistry of isotopic labelling. Procedures are described for labelling specifically with radio-carbon and tritium a wide variety of substances at present of interest. The list includes several α-amino-acids, γ-amino butyric acid, actinomycin, indan, *cis*-octenoic acid and nicotine. Recoil labelling and labelling by heterogeneous exchange on gas chromatographic columns are discussed in several articles, and also side reactions occurring during Wilzbach exchange labelling with tritium. Biosynthetic procedures are described for straight-chain hydrocarbons, terpenes, phytosterols, furocoumarins and plant hormones.

More than half the book is concerned with results of biological application of labelled substances. Winchell *et al.* (Berkeley) contribute an outstanding article on the kinetics of iodine-131 plasma proteins in dog lymph and Pinter (Baltimore) does the same for dog kidneys. Major articles by Tolbert *et al.* (Boulder) and Fish *et al.* (San Francisco) deal with results of metabolic studies based on measuring expired $^{14}CO_2$. Biancho *et al.* (Milan) attempt to correlate haem and globin specific activities, and Benassi and Piccotti (Turin) report on the incorporation of tritiated thymidine into ascites tumour cells. The articles are of a generally high standard, but any thread of continuity throughout the volume is scarcely perceptible.

A. S. MCFARLANE

CURARE SENSITIVITY IN NEONATALLY THYMECTOMIZED MICE

By DR. MICHAEL E. BLAW*, PROF. ROBERT A. GOOD†, and DR. RAYMOND D. A. PETERSON‡

Pediatric Research Laboratories of the Variety Club Heart Hospital, and the Division of Neurology, University of Minnesota, Minneapolis

THE correlation of anatomical changes in the thymus with myasthenia gravis has offered hope for a better understanding of the pathogenesis of this disease. Thymectomy has been beneficial in some myasthenic patients, but its failure to alter the disease consistently has tended to obscure the relationship of the thymus to myasthenia gravis. Strauss[1] found that antibodies directed against the *A*-band of striated muscle exist in many patients with myasthenia gravis, but it has not been possible as yet to reconcile these findings with the apparent physiological or anatomical abnormalities that occur at the myoneural junction. Other stigmata of an 'autoimmune' process, however, have been observed in patients with myasthenia gravis, such as circulating anti-nuclear antibodies, antibodies reacting against heart muscle, and against thymic epithelial cells, in addition to the occasional association of myasthenia with diseases considered to be autoimmune, such as ulcerative colitis, hepatitis and lupus erythematosus[2–5]. Following the demonstration that the thymus played an important part in the development of the immune system, Adner *et al.*[6] investigated the capacity of myasthenic patients to manifest delayed hypersensitivity. They found such patients to be quantitatively deficient in this functional indicator of the thymus-dependent lymphoid tissue[7,8].

The occurrence of transitory myasthenia observed in some babies born of myasthenic mothers has suggested that a substance with an action similar to curare may be circulating in the blood of myasthenic patients. However, transfer studies with sera from myasthenic patients utilizing normal human adults and experimental animals as recipients have not yet revealed such a substance[9].

On the basis of these observations of a close association between myasthenia gravis and (1) histological changes in the thymus; (2) an abnormality in function of the immune system; (3) a circulating curare-like substance in the blood, we postulated that the thymus and the thymus-dependent lymphoid tissue might, indeed, be abnormal in patients with myasthenia and that perhaps neonatally thymectomized mice, also deficient in thymus-dependent lymphoid development[10,11], would be more sensitive to curare. In this view the lymphoid system might have, either as a primary or secondary function, the capacity to detoxify certain natural toxins such as curare.

Albino Swiss mice were thymectomized within 24 h of birth and returned to the mother for suckling. Beginning after 4 weeks of age this strain of mice undergoes a rapid wasting disease following the depletion of the lymphoid tissue produced by neonatal thymectomy[12]. At the time that these investigations were carried out the mice were active and healthy in appearance, although their lymphoid tissues were known to be morphologically and functionally deficient. Between 3 weeks and 4 weeks of age the mice were assayed for sensitivity to curare by assessing the loss of the righting reflex according to the technique of Wolf[13]. *d*-Tubocurarine was injected intraperitoneally and the dose calculated on a μg/kg basis. Each animal was tested for loss of righting reflex every 1–2 min. The animal was placed on its side and if unable to attain the upright position within 15 sec the response was considered positive. All operated animals, whether they had a positive or negative response, were autopsied to determine whether the thymus had been completely removed. Animals with any evidence of incomplete thymectomy were not included in the study. Unoperated 3–4-week-old Swiss albino mice served as controls.

A total of 156 thymectomized and 261 control animals were assayed. The dose at which 50 per cent of the animals would be expected to show a positive response (ED_{50}) was 475 μg/kg in the control group, whereas the ED_{50} was 310 μg/kg in the thymectomized mice. The 99 per cent confidence interval for the control group was 396 μg/kg to 570 μg/kg and 248 μg/kg to 388 μg/kg for the thymectomized animals. The data from this experiment are tabulated in Table 1. Probit analysis of the data by the method of Litchfield and Wilcoxon[14] is shown in Fig. 1. The results are significant beyond the $P = 0{\cdot}01$ level and strongly support the contention that mice which are deficient in their thymic-dependent lymphoid tissue are more sensitive to the myoneural blocking effect of curare than are controls.

Table 1. SENSITIVITY OF NEONATALLY THYMECTOMIZED MICE TO *d*-TUBOCURARINE

Dose (μg/kg)	Controls: No. of animals	Controls: Per cent loss of righting reflex	Neonatally thymectomized: No. of animals	Neonatally thymectomized: Per cent loss of righting reflex
101–150			17	0
151–200			16	25·0
201–250	21	0	12	33 3
251–300	22	13·6	17	23·6
301–350	21	14·3	13	69·2
351–400	20	20·0	13	53·8
401–450	21	42·8	11	72·7
451–500	26	42·4	16	62·5
501–550	22	68 0	10	80·0
551–600	20	70·0	14	78 6
601–650	21	62·0	10	90·0
651–700	20	70·0		
701–750	27	76·0		
751–800	20	95 0		

The increased sensitivity to *d*-tubocurarine manifested by neonatally thymectomized mice might be related to the wasting disease that affects these animals after 4 weeks, although at the time the assays were carried out the animals were healthy in appearance, not lymphopenic, and normally active, though their lymphoid cells and tissues are considered to be abnormal by immunological

‡ Established investigator, American Heart Association.

criteria[10–12]. Nevertheless, the incipient wasting disease might have some effect on the myoneural junction, a defect not evident clinically but reflected in the extreme vulnerability to curare. This is difficult to rule out entirely.

Pharmacological studies[15–18] on the distribution and excretion of ^{14}C-labelled *d*-tubocurarine dimethyl ether and other forms of curare in normal animals indicate that 90 per cent of an intravenous dose disappears from the blood within 2 min. Within 24 h up to 91 per cent of the material can be recovered in the urine. Most of the excreted curare in the urine is chemically unchanged and still biologically active. Although paralysis may last but 15 min, within the same 15-min period only 10 per cent of the material is found in the urine. The conclusion drawn from these investigations is that curare is rapidly complexed in the body but slowly released and excreted by the kidneys. Observations of the clearance and excretion of radioactively labelled curare by normal and neonatally thymectomized mice are being made to test the hypothesis of a defect in the complexing of curare in the thymectomized animals.

As our investigations relate to the pathogenesis of myasthenia gravis, the initial hypothesis has gained support. In the human baby most evidence suggests that, although the thymic system as measured by its immune function is qualitatively intact, it is quantitatively deficient[19]. The occurrence of transitory myasthenia in babies of myasthenic mothers may depend, at least in part, on this quantitative deficiency of the thymic component of the lymphoid system and the consequent deficient ability of the baby to complex a postulated humoral substance which has crossed the placental barrier from the mother. The alternative, of course, is the more popular view that the mother produces an auto-antibody which damages the myoneural junction or interferes with its function.

In conclusion, these data demonstrate that neonatally thymectomized mice are more sensitive to curare than control mice when assayed by the loss of righting reflex. It is suggested that the thymus and its thymus-dependent lymphoid tissue may function as a system which, in addition to its immune function, acts in detoxification of certain naturally occurring toxins.

We thank Dr. Nelson Goldberg for his help in the statistical analysis.

A NATURALLY OCCURRING FRAGMENT RELATED TO THE HEAVY CHAINS OF IMMUNOGLOBULIN G IN NORMAL HUMAN URINE

By Dr. M. W. TURNER and Dr. D. S. ROWE

Department of Experimental Pathology, University of Birmingham

In recent years there has been considerable progress in the elucidation of structural, metabolic, and antibody features of the immunoglobulins. It is now known that these proteins are comprised of two varieties of polypeptide chains called heavy and light chains[1], and that the heavy chains differ in the four main classes of immunoglobulins—IgG, IgA, IgM and IgD (refs. 2–4). There are two types of light chains, type *K* and type *L*. Both types are common to all classes of immunoglobulins.

Previous investigations on normal human urine have demonstrated free light chains of both types[5,6] as well as intact IgG and IgA[6,7]. The presence of light chains, and their pathological counterparts, the Bence Jones proteins, is important to considerations of immunoglobulin biosynthesis and metabolism, and a demonstration of other fragments would be of similar interest. This article describes the finding of another immunoglobulin component in normal human urine. This component is related to the heavy polypeptide chains of IgG.

Large volumes of urine were collected from two healthy adult males and stored at 4° C in the presence of 0·1 per cent sodium azide. The urine samples were dialysed overnight against running tap-water, centrifuged to remove cellular debris and then lyophilized. The lyophilized products were reconstituted in 0·2 M *tris*-hydrochloric acid buffer (*p*H 8·0) to 1/200 and 1/120 of their original volumes respectively. Insoluble material was removed by high-speed centrifugation. In the analyses to be described both samples yielded similar results.

The reconstituted urine samples were fractionated by gel filtration on columns of 'Sephadex *G*-200' (ref. 8), using 0·2 M *tris*-hydrochloric acid + 0·2 M sodium chloride (*p*H 8·0) buffer for the elution. A representative elution pattern is shown in Fig. 1. Proteins were eluted from fraction 20 to fraction 60. Albumin was eluted in the region of fraction 40. Appropriate fractions were concentrated four-fold by ultra-filtration, and Ouchterlony gel-diffusion analyses[9] were carried out using antisera specific for the polypeptide chains indicated. IgM and IgD were not detected. IgA was detected in several of the early fractions. Fractions from two regions reacted with the antiserum to the γ-heavy chains of IgG. The activity in fractions 30–36 was due to the presence of intact IgG molecules as has been previously demonstrated[7].

These fractions gave a reaction of identity on Ouchterlony analysis with serum IgG. Fractions 51–58 also precipitated with the antiserum. These fractions showed a reaction of partial identity with serum IgG. The antiserum used in these tests was prepared by immunizing rabbits with the heavy chains of IgG isolated by the method of Franěk and Zikán[10]. On Ouchterlony analysis this antiserum reacted strongly with heavy (γ) chain preparations and also weakly with light chain preparations. Before it was used, the antiserum had been absorbed with the Fab fragments of IgG. No reactivity with light chains could then be detected.

Fig. 1 also shows the distribution of the two types of light chains in the separation. It will be noted that both type *K* and type *L* chains were detected in fractions from the same region as the material reacting with the antiserum apparently specific to the γ-heavy chains. Thus it was of importance to establish whether the reactivity with this antiserum was, in fact, due to heavy chain determinants in these fractions or to some hitherto undetected anti-light chain antibodies in the antiserum.

It is clear from the observations of Nachman and Engle[11] that light chains separated from normal pooled human gamma globulin contain antigenic determinants not detectable in the intact native molecule. These hidden determinants can also be demonstrated in Bence Jones proteins. Antibodies to such determinants could have been present in the anti-heavy chain antiserum used in this investigation, and might not have been completely removed by absorption with Fab. To eliminate this possibility, two further absorptions of the antiserum were carried out. The original antiserum was absorbed to slight antigen excess by a light chain preparation from normal IgG, and by a mixture of type *K* and type *L* Bence Jones proteins. Neither of these absorptions affected the reactivity of the antiserum with the urinary proteins. It is still precipitated with fractions 30–36 and 51–58. The protein in these latter fractions was again found to be antigenically deficient as compared with intact IgG (Fig. 2).

These findings imply that the low molecular weight protein in fractions 51–58 was antigenically deficient not only with respect to intact IgG, but also with respect to the γ-heavy chains of IgG. Ouchterlony analysis (Fig. 3)

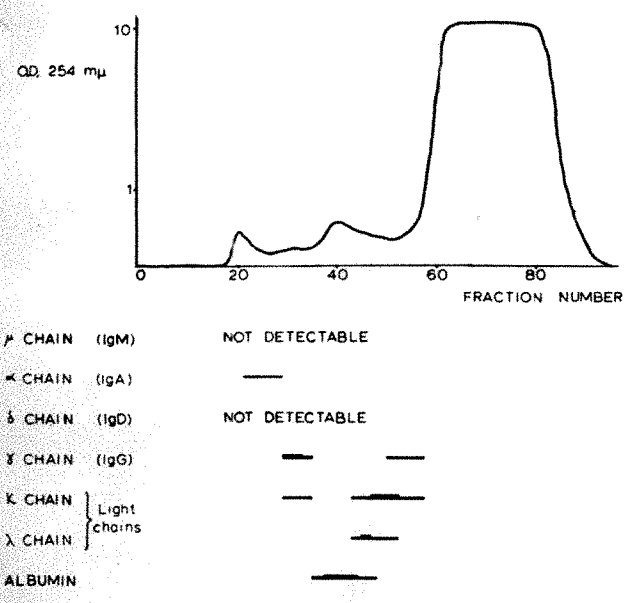

Fig. 1. Elution pattern of gel-filtration of a normal urine concentrate on 'Sephadex G-200'. Optical densities were measured at 254 mμ by a recording spectrophotometer. The final large peak did not contain protein. Shown below as horizontal bars are the distribution ranges of fractions precipitating on Ouchterlony analysis with antisera specific to the indicated immunoglobulin polypeptide chains, and to serum albumin

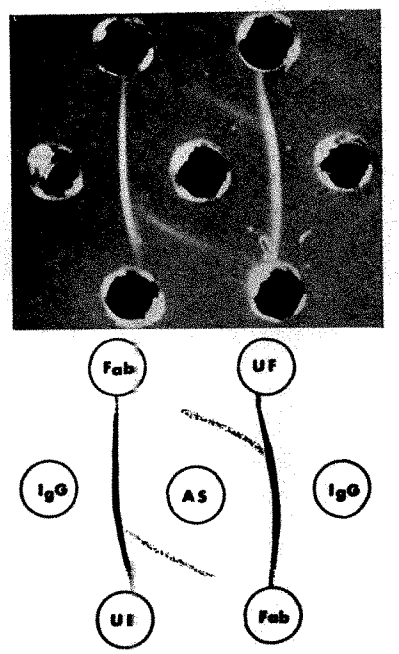

Fig. 2. Ouchterlony analysis showing reaction of partial identity between the low molecular weight urine fractions 51–59 (*UF*) and IgG (1 mg/ml.). The antiserum (*AS*) was specific for γ-heavy chains and failed to react 4 mg/ml., chromium concentration 0·1 mg/ml

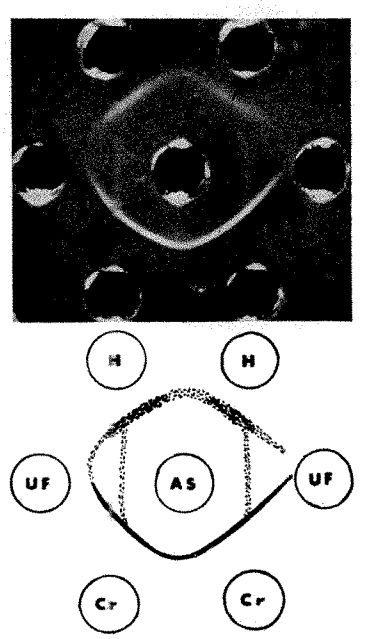

Fig. 3. Ouchterlony analysis showing reaction of partial identity between the low molecular weight urine fractions 51–58 (*UF*) and heavy chains (*H*) prepared from serum IgG. A similar relationship is seen to the abnormal protein (*Cr*) from a patient with heavy-chain disease. The antiserum (*AS*) was specific to γ-heavy chains. Heavy-chain concentration 4 mg/ml., chromium concentration 0·1 mg/ml.

showed that this was the case; a γ-chain preparation formed a clear spur over the low molecular weight urine protein.

Franklin, Lowenstein, Bigelow and Meltzer[12] have described a plasma cell dyscrasia in which there was an excessive production of protein related to γ-heavy chains. It has been shown[13] that this material is not the complete heavy chain, but is similar to the Fc fragment produced by papain digestion of IgG. It was possible that the low molecular weight urine protein was a normal counterpart of this pathological protein. However, the Ouchterlony analysis shown in Fig. 3 excludes this possibility. Using

the antiserum specific to heavy chains, the low molecular weight urine protein was antigenically deficient with respect to the pathological 'heavy chain' protein (Cr) (kindly supplied by Dr. Franklin).

The low molecular weight urine protein was then considered in relation to the fragments of IgG produced by papain digestion. Papain in the presence of cysteine yields two fragments, Fab and Fc, distinguishable by immunoelectrophoresis (Fig. 4). The relationship of these fragments to the peptide chains of the molecule has been elucidated by Cohen[14]. Fab contains the light chains and part of the γ-heavy chains; Fc contains the remainder of the γ-chains, and its antigenic determinants are specific to the γ-chains. Thus, antisera which are Fc specific are also γ-chain specific. The previous results suggest that the low molecular weight urine protein is related but antigenically deficient with respect to Fc.

Using appropriate antisera papain digests of IgG can be shown to contain an additional component which is antigenically deficient with respect to Fc. This fragment has been previously termed F′ (ref. 15) but will here be referred to as Fc′ being consistent with current immunoglobulin nomenclature[3]. Fc′ is distinguished by its anodal mobility on immunoelectrophoresis (Fig. 4).

The relationship between the low molecular weight urinary protein and Fc′ has been determined by comparative immunoelectrophoresis (Fig. 4). These two components appear to be antigenically identical. They are also identical with respect to electrophoretic mobility (Fig. 5). This figure shows that the urinary light chains, although eluted in the same 'Sephadex' fractions, are clearly distinct from Fc′ by their electrophoretic mobility as well as by their antigenic determinants. This indicates that the Fc′ determinants and the light chain determinants are present on different molecules in the urine. No fragments comparable in their electrophoretic mobility and antigenicity with Fab or Fc components were detected in any urine fraction.

Various low molecular weight γ-globulins in plasma and urine have recently been described[16–18]. These proteins, which migrate in the γ-globulin electrophoretic region, are clearly distinct from Fc′ which is of α-globulin mobility. In addition fragments antigenically related to Fc- and γ-chains have been described[6], but these were not identified as Fc′.

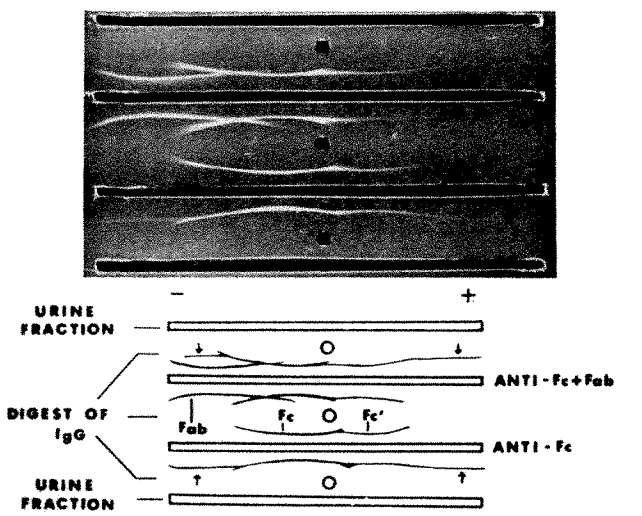

Fig. 4. Comparative immunoelectrophoresis. The three centre wells were filled with papain digest of IgG and electrophoresis was performed. Antisera were then placed in the centre troughs and the low molecular weight urine fractions 51–58 in the outer troughs. The antisera reacted with the urine fractions to produce straight lines indicated by the arrows. These lines fuse with the Fc′ line of the papain digest (antigenic identity), partially fuse with the Fc line (partial identity) and are independent of the Fab line (non-identity)

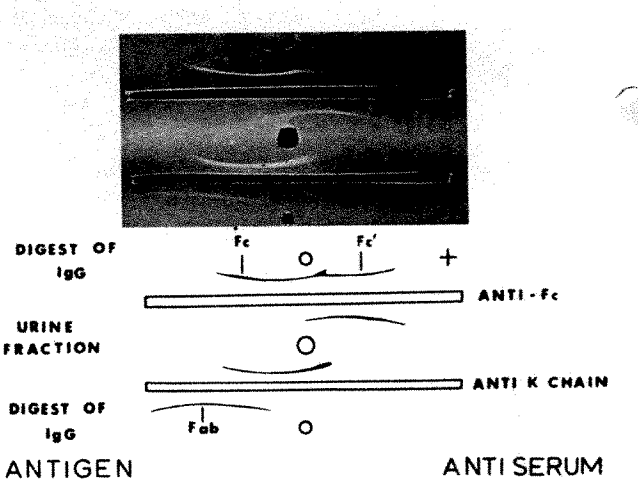

Fig. 5. Immunoelectrophoretic analyses showing that the electrophoretic mobilities of Fc′ from urine and Fc′ in a papain digest of IgG are identical. However, Fc′ differs in its electrophoretic mobility from urinary light chains in the same urine fractions as revealed by the antiserum to kappa light chains. There is no evidence of material with the antigenic and electrophoretic properties of Fc or Fab in the urine fraction

In a study of 'heavy chain disease' Takatsuki and Osserman[19] demonstrated Fc′ as a constituent of the abnormal proteins from four cases, but Fc′ was not detected in the fifth. In a study of myeloma proteins the same authors had similar findings, G-myeloma proteins of class *C* showed Fc′ after treatment with papain and cysteine, whereas in G-myeloma proteins of class *Z* Fc′ were not detectable. Fc′ may therefore be part of some IgG molecules, but not of others.

The Fc′ of normal urine may represent an independently synthesized chain, comparable with light chains. Such material might be present in the plasma and readily excreted in the urine on account of its low molecular weight; it might also be found in larger amounts in serum and urine of patients with certain disorders of immunoglobulin synthesis. Alternatively, Fc′ may be the result of enzymatic degradation of some IgG molecules present in urine. Poulik and Schuster[20] have shown that Fc′ is not produced from IgG by digestion by papain alone, but requires in addition the presence of cysteine. Reducing agents which may be present in urine might, in conjunction with proteolytic enzymes, lead to the separation of Fc′. However, it was notable that other fragments of enzymatic degradation, such as Fc and Fab, were not detected in these studies.

This work was carried out during the tenure of a Medical Research Council junior research fellowship by M. W. Turner. We acknowledge the skilled technical assistance of Miss K. Robinson.

F'c FRAGMENT OF IMMUNOGLOBULINS

By PROF. M. D. POULIK

The Child Research Center of Michigan and the Department of Pediatrics, Wayne State University School of Medicine, Detroit, Michigan

PAPAIN digestion of IgG immunoglobulins yields three main fragments which can be separated by chromatography[1-4]. Two different immunological determinants were localized on the Fab and Fc fragments and afterwards related to the *L* and *H* polypeptide chains of the immunoglobulins[5,6]. The presence of an additional non-dialysable fragment (F') was detected with some antisera[2,7,8]. Starch-gel electrophoresis of the papain digests revealed a marked heterogeneity of the Fc fragments[9-11] of IgG immunoglobulins and IgG myeloma globulins. A group of fast migrating components was found in such digests which were designated as F'c components[12,13]. Isolation and characterization of these components were therefore undertaken.

Cohn fraction-II (Fr-II), IgG gamma globulins of single individuals, γG and γA myeloma globulins as well as free urinary *H*-chain[14] (generous gift of Dr. E. C. Franklin) were digested in papain according to my earlier method[9]. Trypsin digests were also prepared according to Schrohenloher[15]. Papain digests of γ M and cryomacroglobulins as well as of IgG globulins of chimpanzees, rhesus monkeys and slow loris monkeys were also studied.

Agar-gel electrophoresis and immunoelectrophoresis patterns of representative digests are shown in Fig. 1. The F'c component represents only a small portion of the digests as shown by staining (Fig. 1*a*). The precipitin lines developed with several antisera containing anti-Fc and anti-F'c antibodies indicate that the F'c fragment is deficient in at least one antigenic determinant with respect to the Fc fragment (Fig. 1*c*, *d*, *e* and *f*) and the spur formed is less defined in the case of the free *H*-chain (Fig. 1*g* and *h*). The F'c fragment produced by trypsin digestion migrates with lesser mobility than the papain-F'c fragment (Fig. 1*d* and *h*).

Starch-gel electrophoretic and immunoelectrophoretic analysis identified the F'c fragment as migrating immediately behind the 'brown-line' in the discontinuous system of buffers[16]. Three components were readily separated (Fig. 2*A*, *D* and *E*). The fastest of the components is present in the lowest concentration and the slowest in the highest concentration (Fig. 2*A*, *D* and *E*). A fourth, slowly migrating component can be demonstrated when isolated F'c components are analysed at higher concentrations (4–5 per cent). The F'c components obtained by digestion with trypsin differ in mobilities and amounts from those present in papain digests; the free '*H*-chain' of Franklin (Cr type) provides excellent material for such studies (Fig. 2*F*). F'c components were not demonstrated in papain or trypsin digests of γ A myelomas (Fig. 2*B*, *C*), γ M globulins and cryomacroglobulins, but were demonstrated in IgG globulins of the non-human primates. Despite immunological cross-reactivity between the F'c of human and chimpanzee, the electrophoretic mobility of the chimpanzee F'c was considerably less than that derived from human IgG.

Two methods were used to isolate the F'c fragment. The F'c components, fast migrating sub-components of the Fc fragment and a portion of the undigested IgG globulins are not adsorbed on carboxymethyl-cellulose when 0·01 M acetate buffer, *p*H 5·4, is used. This unadsorbed fraction, when rechromatographed on DEAE-cellulose (0·05 M phosphate buffer, *p*H 7·8, followed by 0·2 M phosphate buffer, *p*H 7·8), affords three peaks and

pure F'c fragment is present in the tail portion of the third peak. Kunkel's starch-block electrophoresis[17] is an alternative method to obtain the F'c fragment in pure state (barbital buffer). Ultracentrifugal analysis of the pure F'c fragment (obtained by either method) has shown that this fragment sediments much slower (2·1*S*) than the Fc fragment (3·5*S*). This fragment constitutes about 10 per cent of the intact molecule. With Fr-II digested for 18 h tests for the presence of Gm groups are so far inconclusive.

Mode of production of the F'c was also studied. Human Fr-II was digested with papain in the presence and absence of cysteine for 18 h. The F'c fragment was not produced in the absence of cysteine as shown in Fig. 3*G'*. After this period of time the sample lacking cysteine (*G'*) was divided into two parts and to one part was added cysteine (final concentration 0·01 M) (Fig. 3*a*) and to the other was added fresh papain and cysteine (final concentration of cysteine 0·01 M) (Fig. 3*b*). The mixtures were incubated at 37° C and samples were taken at intervals for immunoelectrophoretic analysis. F'c component was detectable after 2 h (Fig. 3*b*, 2 h) and fully developed after 24 h of incubation (Fig. 3*a* and *b*, 24 h). Thus cysteine in addition to papain is necessary to produce the F'c fragment.

Little attention has been given in the past to F'c fragment in papain digests. This failure is primarily due to its low concentration and the need of special antisera for its detection. Consequently, it is not accounted for in the present models of the gamma globulin molecule.

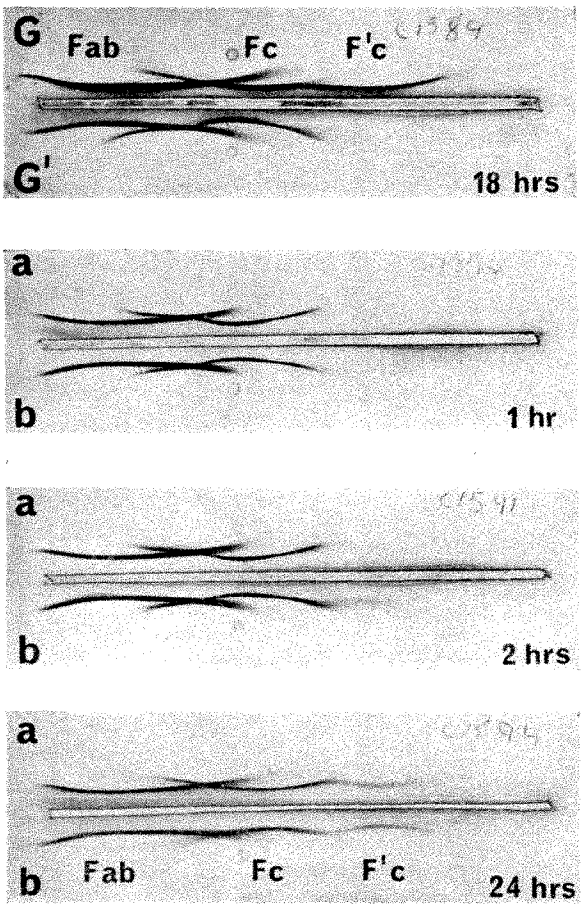

Fig. 3. Immunoelectrophoretic patterns demonstrating the role of cysteine in the development of F'c fragment during papain digestion of Cohn Fr-II. *G*, Digestion in the presence of cysteine, 18 h; *G'*, digestion in the absence of cysteine, 18 h; *a*, cysteine added to *G'*; *b*, cysteine and papain added to G'. Antiserum contains antibodies against Fab, Fc and F'c fragments

The findings presented here show that F'c is derived from the Fc fragment. This notion is supported by the release of this fragment after papain digestion of the free urinary *H*-chain. Since the latter lacks the *A* piece, and consequently a portion of the *H*-chain, this possible source of the F'c fragment can be eliminated. It is generally assumed that papain cleaves peptide bonds near the middle of the *H*-chain. This reaction is probably coupled with reduction of an inter-*H*-chain disulphide bond by the reagents used for activation of the papain. Because there is perhaps only one such bond[18] the prospective region of the *H*-chain from which the F'c fragment may be derived can be anticipated. This region may have a unique amino-acid sequence since the Fc fragment formed contains from nine to eleven separable sub-components[9]. These are of about equal molecular weight, but differ significantly with respect to charge. Their number, mobilities and concentration of each are identical in IgG immunoglobulin and all γ G myeloma so far tested. The simplest explanation of this type of heterogeneity would be by process of sequential cleavage. All these sub-components carry a common antigenic determinant and are structurally complex as previously shown[9,19]. Since the F'c fragment is also heterogeneous (four components) a common origin of both fragments can be envisaged. It has been demonstrated that the Fc fragment obtained by papain alone (in the absence of cysteine) can be separated into four sub-components which migrate with different mobilities than those obtained by digestion with papain in the presence of cysteine[13]. Furthermore, F'c fragment is not formed (compare Fig. 3) under identical conditions in the absence of cysteine[13]. Thus it is feasible that the sub-components produced by papain in the absence of cysteine still contain at least one disulphide bond. When such is reduced, the F'c fragments are formed, the remaining portions of the sub-components rendered more susceptible to papain and additional sub-components derived. A search for the SH-groups of the F'c fragment should be profitable provided it is not destroyed during the reactions.

The F'c fragment carries at least one antigenic determinant in common with the Fc fragment. The fragment is immunologically active even after reductive cleavage in the presence of urea and can be further separated into a number of components in urea starch-gel. The biological functions have not been investigated as yet. As already mentioned, testing for the presence of Gm groups proved disappointing. This may be attributed to the length of time of digestion (18 h). Further tests are under way. The low sedimentation value and lack of hexose provide further evidence that F'c fragment is a definite entity.

This investigation was supported in part by U.S. Public Health Service research grants from the National Heart Institute and the National Institute of Allergy and Infectious Diseases, and in part by a grant from the Children's Leukemia Foundation of Michigan.

USE OF CHARGED THIOL REAGENTS IN INTERPRETING THE ELECTROPHORETIC PATTERNS OF IMMUNE GLOBULIN CHAINS AND FRAGMENTS

By DR. A. FEINSTEIN

Agricultural Research Council Institute of Animal Physiology, Babraham, Cambridge

THE immune globulins of serum consist of light and heavy polypeptide chains[1,2]. When the light chains are separated and examined by electrophoresis in alkaline starch-gel containing 8 M urea, they form a pattern of equally spaced bands[3] as shown in Fig. 1*a*, *h*. Bence Jones proteins, which appear in the urine of patients with multiple myeloma, are known to be relatively homogeneous light chains[4] and each in electrophoresis forms mainly a single band, corresponding to one or other of the normal light-chain bands. Considerable differences in amino-acid sequence have been found (within a stretch of the N-terminal half) between different Bence Jones proteins[5–7]. This suggests a simple explanation for the origin of the banding patterns of the light chains. Variation in the proportion of basic and acidic residues of light chains will result in variation in electrophoretic mobility. If light chains in the electrophoresis medium are of almost identical size and shape, chains with identical net charge should travel as a single band, even where they differ in amino-acid composition. Thus, even a very heterogeneous population of chains would yield only a limited number of well-defined bands in electrophoresis, if variations in residues partially ionized at the gel *p*H are relatively infrequent. This explanation predicts that chains in neighbouring bands will only differ by a single charge. This can be tested, because if a single carboxyl group can be added to a light chain it should alter its electrophoretic pattern by a single band spacing. In the following experiment, such a shift was in fact observed.

The charge increment was added to several Bence Jones proteins by carboxymethylation of a cysteine residue with iodoacetate. It was necessary first to reduce them partially with 2-mercaptoethanol as Bence Jones proteins exist partly as disulphide-bonded dimers[8], and even unreduced monomers have a cysteine residue blocked with a lone half-cystine[9]. After treatment with 0·15 M 2-mercaptoethanol for 1 h in *p*H 8·2 *tris* buffer, part of each preparation was then made 0·3 M in iodoacetate, and the remainder was made 0·25 M in iodoacetamide. After 3 h at 0° C, the preparations were dialysed against cold saline and then examined by electrophoresis in starch-gel containing glycine buffer, *p*H 8·5, 0·05 M with 8 M urea. In Fig. 1 comparison of the relative positions of the two preparations of a type *K* Bence Jones protein (Rad.), *b* and *d*, with normal light chains, *a* and *h*, shows that carboxymethylation has altered the position of the main band and faint neighbouring bands by a single-band spacing. The extent of carboxymethylation was confirmed by estimating in a Spinco amino-acid analyser the amount of carboxymethyl-cysteine liberated after hydrolysis for 24 h in 6 N hydrochloric acid at 106° C *in vacuo*. 1·02 moles of carboxymethyl-cysteine were recovered per 20,000 g, and 3·5 half-cystine residues were also recovered. Thus a single charge per chain had been introduced, resulting in a mobility shift of a single-band spacing. Confirmation of the nature of light chain banding was obtained by introducing carboxyl groups randomly into Bence Jones proteins by prolonged treatment with iodoacetate at *p*H 10 after reduction. Treated thus, Rad. generated a pattern of bands, Fig. 1*c*, perfectly mimicking those of normal light chains.

Among the type *L* proteins tested was one (Pet.) which altered its position after carboxymethylation by two spacings (Fig. 1*e* and *g*) suggesting that two cysteine residues per chain had been carboxymethylated. Gel-filtration in 1 M propionic acid in a 'Sephadex *G*-100' column showed that 75–80 per cent of Pet. chains exist as disulphide-bonded dimers. The remaining monomer chains also have one sulphydryl radical which cannot be titrated due to the fact that it is linked to a half-cystine[9]. Yet by spectrophotometric titration of Pet. with *p*-chloromercuribenzoate before reduction, a further 0·8 sulphydryl group per chain was estimated. No such titratable groups were found in any of the other Bence Jones proteins examined. This suggests that Pet. chains must have two cysteine residues which are not involved in intra-chain bonds, as compared with the single cysteine residue more common in light chains. To confirm this, a sample of Pet. was treated with iodoacetate to charge the free sulphydryl group, then with 2-mercaptoethanol and iodoacetamide to liberate and to block the second sulphydryl group (Fig. 2*c*). With a second sample the sequence of iodoacetate and iodoacetamide treatments was reversed to charge only the sulphydryl group released after reduction (Fig. 2*a*). The effect was, as predicted, to

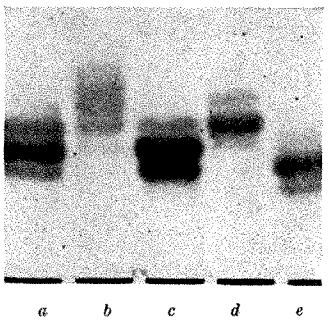

Fig. 2. Comparison of treated Pet. samples: (*a*) iodoacetamide treated, reduced and iodoacetate treated; (*b*) randomly carboxymethylated; (*c*) iodoacetate treated, reduced and iodoacetamide treated; (*d*) reduced and iodoacetate treated; (*e*) reduced and iodoacetamide treated

produce in each case a shift of only a single spacing in the pattern. The earlier pair of preparations demonstrating the full double shift is shown in Fig. 2*d* and *e* for comparison. It can be seen that part of the sample (in the slowest band of Fig. 2*c*) has failed to alter its behaviour after treatment with iodoacetate. Thus some Pet. chains have no reactive sulphydryl groups before reduction, as had, in fact, been indicated by the *p*-chloromercuribenzoate titration. Two observations suggest that these are dimer chains. Milstein found that after performic oxidation of

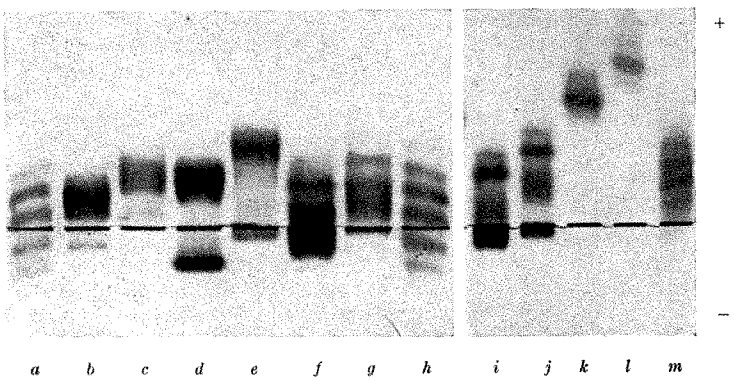

Fig. 3. Effect of carboxymethylation on patterns of myeloma chains: (*a*, *h* and *m*) normal human light chains. IgM Hu. reduced and (*b*) iodoacetamide treated; (*c*) iodoacetate treated. IgM Ma. reduced and (*d*) iodoacetamide treated; (*e*) iodoacetate treated. IgG Tu. reduced and (*f*) iodoacetamide treated; (*g*) iodoacetate treated. IgG Wr. reduced and (*i*) iodoacetamide treated; (*j*) iodoacetate treated. Bence Jones Pet. reduced and (*k*) iodoacetamide treated; (*l*) iodoacetate treated. Lower bands in IgM patterns and upper bands in IgG patterns are light chains

bonded Pet. dimers, 0·24 residues of cysteic acid were released per chain[9] (Milstein referred to Pet. as 'X'). Also, investigations at present being carried out to locate the free sulphydryl group, using radio-labelled iodoacetate, indicate less labelling of dimer than of monomer chains.

One of the advantages of the aforementioned method of estimating sulphydryl groups is that, in heterogeneous systems, each component which can be electrophoretically resolved can be titrated separately without previous purification. Other methods tend only to give a mean value. In this way the method has proved useful in looking at the constituent chains of myeloma proteins. In Fig. 3 are shown examples of two macroglobulin (IgM) and two IgG preparations. Each preparation had been reduced and treated with iodoacetamide or iodoacetate, as described earlier. In each case the light chain band was moved forward by a single spacing, indicating the release of a single light-chain sulphydryl group by reductive cleavage. No light chains released from the immune globulins examined so far have exhibited a multiple shift resembling that of Bence Jones Pet.

In those samples where the heavy-chain sulphydryl groups released by reduction were carboxymethylated, these heavy chains also, of course, differed in mobility from the corresponding chains treated with iodoacetamide (Fig. 3). When milder conditions of carboxymethylation were used (Fig. 4 ii) employing 0·2 M iodoacetate for 1 h, although all heavy chains reacted, as judged by their altered position, the light chains were only partially carboxymethylated. This relatively slow reaction of the light chain cysteine may result from charge repulsion due to its being, or neighbouring, the C terminal residue[10]. These conditions were also inadequate for Bence Jones protein carboxymethylation, and were replaced by the more vigorous treatment described earlier.

Fortunately in some cases the heavy chains were resolved into banded patterns. We have seen such banding in IgA, IgG and IgM heavy chains from myeloma proteins. In Fig. 4 (i) the patterns of heavy-chain preparations from one fast IgG (Re.) and two slow IgG (Tu. and Wr.) myeloma proteins all resolve into bands. Neighbouring bands are separated by rather less than half the light chain spacing. Normal human IgG heavy-chain preparations do not resolve into bands, but those of heavy chains isolated from slow bovine IgG, seen in Fig. 4 (iii), are similarly spaced relative to bovine light chains.

In Fig. 4 (ii) the first two patterns are of reduced macroglobulin. Here the heavy-chain bands are evident, and their spacing is even closer than that of IgG heavy chains, being a third of the light-chain spacing. The effect of iodoacetate has been to preserve the band pattern, but move it forward four spacings. Since similar treatment has been shown to carboxymethylate four cysteines per IgM heavy chain[11,12], this strongly suggests that heavy chains in neighbouring bands, like light chains, differ by a single electronic charge. This would be consistent with the fact that the spacings of light chains and heavy IgG and IgM chains are in inverse relation to their molecular weights, which are respectively approximately 20,000, 50,000 and 70,000 (refs. 12–15). Support for this relation comes from examining the Fab fragment of IgG (ref. 16), with a molecular weight of 42,000 (ref. 13), formed by treatment with papain. This important fragment carries in antibodies a single antigen-binding site. Composed of a light chain with a molecular weight of 20,000, and part of the heavy chain (Fd fragment)[17], with molecular weight of 22,000, its band spacing resulting from net single charge differences should be half that of light chains. Reductive cleavage to light chains and Fd fragments should then convert the pattern to normal light-chain spacing. That this change is in fact observed may be seen in Fig. 5 (i), where the patterns of three bovine Fab preparations from different IgG components are shown before and after reduction. Rabbit Fab preparations also form band patterns[18], and it is remarkable that they have a similar spacing to light chains. That is to say, each fragment with a molecular weight of 40,000 must differ from that in a neighbouring band by two charges, resembling in this the behaviour of symmetrical light-chain dimers. This could only result from allied variations in both light chain and the Fd region of the heavy chain, restricted in both chains of each molecule to those having parallel effects on mobility. Evidence that the more acidic rabbit Fab fragments yield more acidic Fd fragments and light chains has been presented in an earlier communication[18]. It is not clear what biosynthetic mechanism could lead to such parallel variations, and it is clearly important to confirm the observation in other species. A similar preliminary finding for chromatographically purified human Fab fragments from the two slow IgG myeloma proteins Tu. and Wr. is shown in Fig. 5 (ii). As in the rabbit,

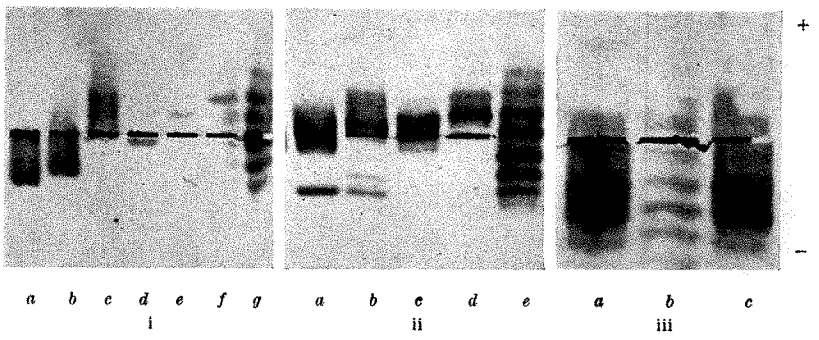

Fig. 4. Electrophoretic patterns showing heavy chain bands. (i) Separated human chains: (*a*) Wr. heavy chain; (*b*) Tu. heavy chain; (*c*) Re. heavy chain; (*d*) Wr. light chain; (*e*) Tu. light chain; (*f*) Re. light chain; (*g*) normal human light chains. (ii) Reduced myeloma proteins: IgM Ma. reduced and (*a*) iodoacetamide treated; (*b*) iodoacetate treated. IgG Re. reduced and (*c*) iodoacetamide treated; (*d*) iodoacetate treated; (*e*) normal human light chains. (iii) Separated chains of bovine IgG2: (*a* and *c*) heavy chain; (*b*) light chain

reduced Fab fragments from slow human IgG globulins resolve electrophoretically into a more acidic light chain, and a less acidic Fd heavy-chain fragment. In the two myeloma patterns shown, the lowest bands are Fd, the upper bands light chains, and some remaining intact Fab is detectable midway between them. The different positions of the relatively homogeneous Fd bands confirm that the Fd region is truly variable, rather than subject to variable papain splitting. Considering the many alternative pairs of Fd fragments and light chains which might in principle have combined to form Fab fragments having the observed mobility difference, the parallelism in fact found here in mobility difference between Fab fragments, light chains and Fd fragments is interesting. No general conclusion can, however, be drawn until many more reduced Fab preparations from the same heavy-chain sub-class have been compared.

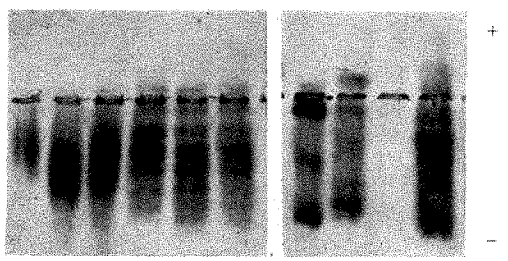

Fig. 5. Reduction of bovine and human Fab fragments. (i) Bovine Fab patterns: (*a*) Preparation from IgG2 and (*d*) same after reduction and iodoacetamide treatment; (*b*) preparation from slow IgG1 and (*e*) same after reduction and iodoacetamide treatment; (*c*) preparation from fast IgG1 and (*f*) same after reduction and iodoacetamide treatment. (ii) Human Fab preparations reduced and iodoacetamide treated: (*a*) Wr.; (*b*) Tu.; (*c*) normal IgG. Lowest bands are Fd fragments, upper bands are light chains. Fd fragments of (*c*) form diffuse unbanded zone

More recently we have been using electrophoresis in agar-gel cooled with petroleum ether[19] to measure mobility changes. This has the advantage of yielding results in an hour, and requiring very little material. For example, it was possible to confirm the titration of Pet. with *p*-chloromercuribenzoate by following the mobility change, using a total of only 10 μl. of 1 per cent Pet. solution. Analytical ultracentrifugation showed that the Bence Jones proteins studied travel as dimers in the aqueous buffer used in the agar-gel. Rad. dimers begin to dissociate at concentrations of less than 0·2 per cent, and the dissociation curves of the native protein and of reduced Rad. treated with iodoacetate or iodoacetamide are almost identical. This suggests that although cysteines that are capable of reacting with the carboxymethyl radical can come sufficiently close to form a disulphide bridge, they are so placed away from the hydrophobic surfaces involved in dimerization that, following carboxymethylation, no forces which could make the dimer unstable are introduced with the ionized groups. The mobility relationships observed for reduced Bence Jones protein in urea starch-gels hold also in aqueous buffers in agar gel. Fig. 6 shows, for example, the agar-gel patterns of Pet. and Rad. separated by three times the spacing distance observed for a single charge increase per chain in carboxymethylated Rad., just as they were in urea starch-gel. This implies that no charged residues become exposed when passing from the folded dimers in agar-gel to the monomer[18] partially unfolded in 8 M urea starch-gel. This concurs with the finding that buried ionized side-chains are absent from the models of myoglobin, lysozyme and all the known haemoglobin variants[14,15].

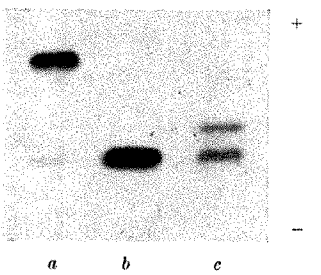

Fig. 6. Agar-gel electrophoretic patterns of Bence Jones proteins. Reduced and iodoacetamide treated: (*a*) Pet.; (*b*) Rad.; (*c*) Rad. reduced and partially iodoacetate treated

I thank Dr. D'A. Kok and Dr. P. Lachmann for samples of urine and serum, and J. Herbert for technical assistance.

TRANSPLANTATION IMMUNITY: LOCALIZATION IN MOUSE SERUM OF ANTIBODIES RESPONSIBLE FOR HAEMAGGLUTINATION, CYTOTOXICITY AND ENHANCEMENT

By DR. GUY A. VOISIN, RADSLAV G. KINSKY and FRANZ K. JANSEN*
Centre d'Immuno-Pathologie de l'Association Claude-Bernard et de l'INSERM, Hôpital Saint-Antoine, Paris

IMMUNE reactions to transplantation antigens result in several effects on cells bearing the corresponding antigens. Since Gorer developed, with Mikulska, the well-known immune haemagglutination test in 1954[1], a great deal of work has been done to detect various antibody responses in mice exposed to allogeneic antigens. Mouse antisera reacting specifically with transplantation antigens have been further studied for their cytotoxic effect, in the presence of complement, on lymphoid and tumoral cells from the immunizing strain[2]. Another biological effect is known, in the field of transplantation, to be produced by specific immune sera on tumoral[3] and even normal[4] tissues—the enhancement or facilitation phenomenon.

In this preliminary work, we have attempted to ascertain whether these three immunological effects on target cells bearing the corresponding transplantation antigens are attributable to one and the same immunoglobulin acting under different conditions, or if two or more immunoglobulins are involved. In the latter case, it would be relevant to know whether each one is responsible for one of the three biological effects.

* Under a fellowship from NATO attributed by the DAAD from Bonn (Germany).

Sixty female mice of the B_{10}–D_2 line were immunized by a course of injections with A/Jax spleen cells and their serum pooled after the last booster. The pool was divided into two parts: one was investigated without further modification; the second was fractionated by separative electrophoresis into twenty-six fractions. Haemagglutination of A/Jax erythrocytes and cytotoxicity against A/Jax spleen cells were studied both for the complete serum and for the individual electrophoretic fractions. Haemagglutination titre was expressed as the last dilution giving a clear positive agglutination. Cytotoxic power was expressed as the percentage of cells unable to exclude trypan blue after standard incubation with fractions diluted 1/1 and 1/2, plus guinea-pig complement; a total of one hundred cells was counted for each dilution.

Because of the limited amounts, fractions were paired and eight of the 'double fractions' of different electrophoretic mobility were assayed for enhancing properties in eight groups of mice: a volume of 0·1 ml. of complete serum or of serum fractions was injected intravenously into B_{10}–D_2 males in order to test passive enhancement of sarcoma I.

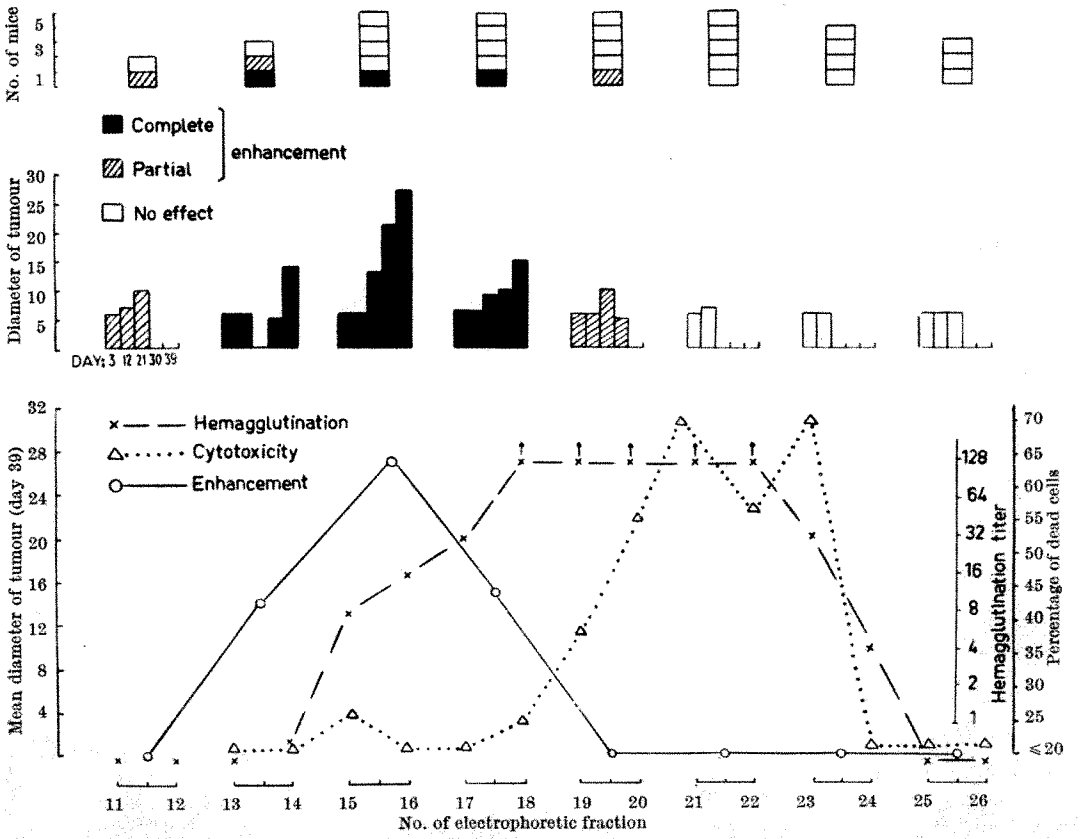

Fig. 1. Biological properties of antibodies: electrophoretic separation. Fractions were examined individually for haemagglutination and cytotoxicity; they were pooled in pairs for the study of enhancing properties. 'Complete' enhancement of a tumour indicates that it resulted in the death of the recipient allogeneic mouse; 'partial' enhancement indicates a tumour of maximum diameter ⩾9 mm; 'no effect' indicates tumours with a maximum diameter ⩽7 mm. The mean diameter of the most conspicuous tumour was taken in each group on days 3, 12, 21, 30 and 39. The mean diameter on day 39 was used for the evaluation of the degree of enhancement because three 'enhanced' mice died (from the tumour) after this period of time. In cytotoxicity tests, the percentage of dead cells in each preparation was taken as an expression of the intensity of cytotoxicity; the base line of 20 per cent is superior or equal to controls and to the inactive fractions

Twenty-four hours later, these mice received a single subcutaneous injection of 10^7 ascites sarcoma I cells, carried by the indigenous *A/Jax* strain. In order to localize the different immunoglobulins in the sequence of fractions an immunoelectrophoretic study of the paired fractions was undertaken with rabbit antisera giving specific precipitation lines with four mouse immunoglobulins: IgG, IgM, IgA and IgY (refs. 5 and 6).

The intact, non-fractionated pool of B_{10}–D_2 anti-A sera had a haemagglutination titre of 1 : 2,050, a cytotoxic power giving 31 per cent of cell death on A lymphoid cells and an enhancing capacity resulting in lethal growth of five tumours out of fourteen implanted in fourteen mice (while the normal rate of take in control mice within the same conditions is, in our experience, lower than 1 out of 30).

Electrophoretic fractionation of the pool and examination for the haemagglutinating, cytotoxic and enhancing activities of the fractions lead to the results expressed in Fig. 1. Fraction 11 is the fastest of the fractions studied for biological activity and fraction 26 the slowest. The anti-A haemagglutinating activity extends from fraction 15 to fraction 24 with a maximum between 18 and 22. The anti-A cytotoxic activity (with added guinea-pig complement) is found in the slow part (from fraction 19 to fraction 23, with a maximum between 20 and 23), while the 'anti'-A enhancing-facilitating activity is found in the fast part (from fraction 13+14 to fraction 17+18, with a maximum at fraction 15+16), even before the appearance of detectable haemagglutinating activity. In view of the small number of mice submitted to the action of each pair of fractions, it was felt necessary to require several criteria for enhancement: proportion of animals with a tumour growing over a certain average (8 mm); mean diameter of tumours in a given group of mice; growth curve of individual tumours and deaths of mice from growing tumours. These criteria have been taken into account in Fig. 1.

The paired fractions still available after enhancement experiments were submitted to immunoelectrophoresis using two rabbit antisera active against the four immunoglobulins known to be present in mouse serum. The results, summarized in Table 1, suggest a possible association of cytotoxic antibodies with IgG and of enhancing antibodies with IgY (if not with IgM). However, the fact that the more cytotoxic fractions (21 and 22) and the more enhancing fractions (15+16) were no longer available for immunoelectrophoretic analysis prevented us from gaining a final answer.

Table 1. TYPES OF IMMUNOGLOBULINS PRESENT IN THE ELECTROPHORETIC FRACTIONS STUDIED FOR BIOLOGICAL ACTIVITY

Type of immunoglobulin	Presence in the following electrophoretic fractions					
	11+12	13+14	15+16	17+18	19+20	21+22	23+24	25+26
IgG	−	±	++	+++	++	+
IgA	−	±	+	+	−	−
IgM	±	+	−	−	−	−
IgY	+	+++	+	+	−	−

The intensity (± to +++) represents a semi-quantitative evaluation. It is based on (1) the inverse distance between the trough and the precipitation line and (2) the intensity of the precipitation line. Fractions 15+16 and 21+22 were not available for analysis.

The main result of this investigation resides in the electrophoretic separation of three biological activities involved in transplantation immunity reactions; cytotoxic activity in the slower fractions, enhancing activity in the faster fractions (almost without detectable overlapping) and haemagglutinating activity in almost the whole spectrum. These findings are reminiscent of the description of the γ_1 (fast) and γ_2 (slow) types of IgG described in guinea-pig[7] and in mouse[8] sera.

In both instances, the slow fractions were capable of haemagglutination and complement fixation while the fast fractions were capable of haemagglutination, incapable of complement fixation and capable of another biological activity: conferring anaphylactic sensitivity to the same species or conferring immunological protection to the target cells. To go further would require the identification of the responsible immunoglobulins. Our results, although suggestive, do not allow firm conclusions in that respect since, while the higher concentration of IgY is in the enhancing fractions, the same fractions also contain the three other immunoglobulins.

We thank Dr. Jean Maillard for help in fractionating the serum and Dr. G. Hermann for providing the anti-mouse immunoglobulin sera and for helping us to interpret the immunoelectrophoretograms.

PRODUCTION OF GRAFT-VERSUS-HOST DISEASE IN THE RAT AND ITS TREATMENT WITH CYTOTOXIC AGENTS

By PROF. G. W. SANTOS* and PROF. A. H. OWENS, jun.

Department of Medicine, Johns Hopkins University, School of Medicine, and Oncology Service, Department of Medicine, Baltimore City Hospitals, Baltimore, Maryland

CYCLOPHOSPHAMIDE (CY) is a potent immunosuppressive drug in the mouse[1], rat[2–4] and man[5]. We have noted also that hybrid adult mice injected with parental, allogeneic or xenogeneic immuno-competent cells following a preliminary injection of CY will show a graft-versus-host reaction[6]. The present report presents preliminary observations on the induction and treatment of a graft-versus-host reaction in the CY pretreated rat.

Female Lewis and *BN* rats, age 10–12 weeks, were used as recipients and donors, respectively. Recipient animals were given a single intraperitoneal injection of 100 mg/kg of CY (about 60 per cent of the LD_{50} for 30 days observation) 4 h prior to the intravenous injection of allogeneic cells. The animals were observed daily and weighed periodically.

Groups of Lewis rats were injected with CY and 4 h later were given graded doses of nucleated bone marrow, blood or spleen cells suspended in Tyrode's solution. The incidence of dermatitis and mortality observed over a 30-day period is recorded in Table 1.

Lewis rats given 64×10^6 nucleated *BN* spleen cells, or 32×10^6 blood cells, intravenously regularly developed a fiery red and oedematous dermatitis involving the ears, paws, tail and to a lesser extent the snout, characteristic of graft-versus-host disease in the rat[7–9], 7–9 days after cell transfer. The dermatitis, with rare exception, persisted until death of the animal or from 10 to 30 days (15 day average) in animals that recovered. After 4–5 days, the dermatitis frequently evolved to desquamation and hair loss (particularly about the snout). In a few animals splinter-like haemorrhages were seen in the skin of

MTX	0·50	7, 9, 11	8/8	8/8
Cort.	20·00	7, 8, 9, 10, 11	8/8	7/8
CY	5·00	2, 3, 5	7/7	2/7*
CY	10·00	2, 3, 5	10/18*	2/18*
CY	5·00	7, 8, 9, 10, 11	7/8	8/8
CY	10·00	7, 9, 11	7/8	4/8
Cells alone		—	45/45	37/45
No cells		—	0/27	3/27

*Incidence of dermatitis or mortality significantly less ($P < 0.05$) than the control by the χ^2 test.

the ear. Diarrhoea occurred occasionally, but was not a common clinical manifestation. The rats rapidly lost about 15–20 per cent of their original body-weight by 15–20 days after cellular transfer. The few animals destined to survive regained their original body-weight over the next 10–14 days. The majority of animals died 10–20 days after the injection of *BN* cells. Further mortality was only rarely seen when animals were observed for periods up to 60 days. This syndrome of pronounced weight loss and dermatitis resulting in high mortality was not seen in CY-injected rats that received saline, syngeneic spleen cells, or heated allogeneic spleen cells.

The data in Table 1 indicate that nucleated cells derived from bone marrow, although less effective than spleen and blood, were capable of inducing graft-versus-host disease. Furthermore, the data suggest that nucleated cells from peripheral blood were more potent than those from spleen in causing the disease. Finally, the incidence of dermatitis and/or mortality was dependent on the dose of cells injected for blood and spleen.

Table 2 records the results of intraperitoneal injections of cortisone (Cort.), methotrexate (MTX) and *cyclo*phosphamide (CY) on the incidence of dermatitis and mortality in CY-pretreated Lewis rats injected with 64×10^6 *BN* spleen cells.

The entries marked with an asterisk in Table 2 indicate treatments that had a beneficial effect on the course of the disease. Methotrexate was able to reduce both the incidence of dermatitis and mortality when begun 2 days after the cell transfer. Treatment with this agent initiated 7 days after cell transfer did not lower mortality nor did it appear to alter noticeably the subsequent course of the dermatitis. *Cyclo*phosphamide reduced the mortality and incidence of dermatitis (the latter only at the higher dose) when begun 2 days after cell transfer. In addition, CY given 7, 9 and 11 days after the injection of *BN* cells appeared to reduce the severity of the dermatitis. The observed reduction in mortality, however, was not significant ($P > 0.05$) when compared to the control by the χ^2 test. Cortisone in the one dose schedule used was ineffective in reducing the mortality or the subsequent course of the dermatitis.

None of the surviving animals from the foregoing groups was a chimera—as tested by the rejection time of full thickness *BN* skin grafted 60 days after the induction of the disease. A more detailed investigation regarding the duration of the chimeric state in animals such as these is at present being carried out.

The graft-versus-host disease described here is easily produced in the adult rat with drug pretreatment which in itself entails very little mortality. Dermatitis is striking and regular in appearance and provides a valuable guide as to the course of the disease. For these reasons, it is felt that this system is particularly well suited for the investigation of therapy directed toward modifying graft-versus-host disease in the adult rat.

A POSSIBLE HOMEOSTATIC MECHANISM IN COMPLEMENT FIXATION: INHIBITION OF THE ACTIVITY OF FIXED C'_1 BY THE FIXATION OF C'_{3a}

By DR. P. J. LACHMANN
Department of Pathology, University of Cambridge

FOR the study of the reactivity of conglutinin and immuno-conglutinins with fixed guinea-pig complement[1] alexinated intermediates at various stages of the complement reaction sequence were prepared as outlined in Fig. 1.

It was of course necessary to confirm that the intermediates formed did show the reactivity expected of them. The test systems used are outlined in Table 1 and are discussed more fully elsewhere[1].

There is one very surprising result in Table 1. The intermediate EAC'_{143a} failed to react with C'_2 to give an intermediate lysing with C'_{EDTA}.

Two explanations for this lack of reactivity were considered. First, the C'_{H62} may contain the C'_1 inhibitor as described by Lepow and Leon[3]; secondly, the fixation of C'_{3a} itself may give rise to inhibition of the reaction with C'_2.

The first explanation is less likely in that the C'_1 inhibitor was reported to be destroyed at 63°. It was, however, tested by decaying EAC'_{142} to EAC'_{14} at 37° for 75 min prior to reaction with C'_{H62}. In these conditions C'_1 inhibitor should still react with C'_1 whereas C'_{3a} will not be bound. It was found that EAC'_{14} treated with C'_{H62} reacted with C'_2 at the same dilution as untreated EAC'_{14}; a finding that was regarded as excluding the participation of a C'_1 inhibitor.

It was, therefore, thought likely that the fixation of C'_{3a} itself was responsible for the inhibition. Now, it is shown in Table 1 that the concentrated *R4* reagent did lyse EAC'_{143a}. The C'_4 in this intermediate thus seems to be

fully active, and the inhibition must, therefore, be of C'_1. This conclusion was supported by testing with the *R*4 reagent after absorption with 5 mg/ml. of an antigen–antibody precipitate (ovalbumin–rabbit anti-ovalbumin) for 15 min at 37°. This treatment removes C'_1 from the *R*4 but—in the absence of C'_4—has little effect on the other C′ components. This reagent produced lysis of EAC'_{14} but again failed to lyse EAC'_{143a}.

Table 2 summarizes these results.

Thus when C'_{3a} is bound on to EAC'_{142} and the C'_2 then allowed to decay, the intermediate formed will no longer react with further C'_2. It has been shown that this inhibition affects C'_1 rather than C'_4 activity and that it is not due to the presence of a C'_1 inhibitor which will react with EAC'_{14}. One is, therefore, led to the conclusion that the fixation of C'_{3a} leads to the inhibition of the activity of the C'_1 already bound. It has not so far been determined whether the C'_1 is actually eluted from the alexinated complex or if it is inactivated *in situ*. The inhibition does not appear to extend to the fixation of further C'_1 since the fixed C'_4 is still active.

This inhibition can be pictured as a feed-back mechanism for regulating the extent of 'long-term' complement fixation at a particular complement-fixing site. When C'_1 has been inactivated no more C'_2 can be fixed so that, when the C'_2 already fixed has decayed, no further fixation of C'_3 components will occur.

The fixation of C'_{3a} is known to be biologically a highly significant step in complement fixation, the EAC'_{1423a} intermediate being that participating in phagocytosis[4],

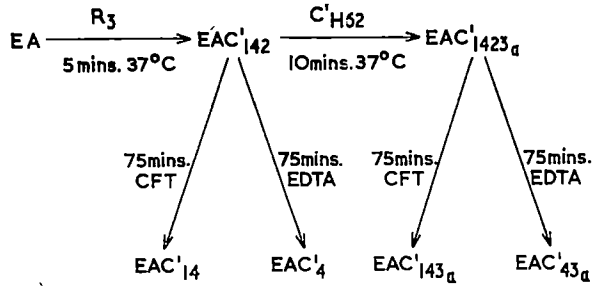

Fig. 1 Preparation of alexinated intermediates. EA, Sheep erythrocytes sensitized with rabbit antibody; R_3, 'Zymoxan'-absorbed guinea-pig serum; C'_{H52}, guinea-pig serum heated at 62° C at *p*H 8·5 for 20 min[3], CFT, complement fixation test diluent (Oxoid), EDTA, 0 01 M EDTA in saline, *p*H 7·2

Table 1. CHARACTERIZATION OF ALEXINATED INTERMEDIATES

Test system	Test for presence on cell of	Alexinated intermediate: EA	EAC'_{142}	EAC'_{14}	EAC'_4	EAC'_{1423a}	EAC'_{143a}	EAC'_{43a}
Lysis with 1/40 *R*4	C'_4	0	100	100	100	100	100	100
Lysis with C'_{EDTA}	C'_{42}	0	100	0	0	100	0	0
Lysis with C'_2 followed by C'_{EDTA}	C'_{14}	0	*	100	0	*	0	0
Lysis with 1/400 *R*4	C'_{43a}	0	0	0	0	100	0	0
Conglutinin	C'_{3a}	–	–	–	–	++	++	++

0, No haemolysis; –, no conglutination; 100, > 50 per cent haemolysis; ++, strong conglutination; *, test not applicable because intermediates lyse with C'_{EDTA} *per se*; *R*4, guinea-pig serum treated with 0 1 M ammonia at 37° C for 45 min; C'_{EDTA}, 1/50 guinea-pig serum in 0 01 M EDTA saline; C'_2, fraction of guinea-pig serum prepared by chromatography on DEAE cellulose[1].

Table 2. FURTHER CHARACTERIZATION OF ALEXINATED INTERMEDIATES

Test system	Test for presence on cell of	Alexinated intermediate: EAC'_{14}	EAC'_{14} treated with C'_{H52}	EAC'_4	EAC'_{143a}
Lysis with 1/40 *R*4	C'_4	100	100	100	100
Lysis with 1/20 *R*4 absorbed with antigen antibody complexes	C'_{14}	100	100	0	0
Lysis with C'_2 followed by C'_{EDTA}	C'_{14}	100	100	0	0
Conglutinin	C'_{3a}	–	–	–	++

The symbols are used as in Table 1

immune adherence[5], and conglutination[6]. A homeostatic mechanism regulating the extent of fixation of this component would, therefore, make good biological sense.

It should, perhaps, also direct attention to the *in vivo* significance of 'long-term' complement fixation, that is, those processes which continue after the initial rapid reaction sequence leading to haemolysis and which have received virtually no attention in the past.

I thank Mrs. Diana Elias for her assistance, and Dr. R. R. A. Coombs and Mr. P. M. Henson for their advice. The work was supported by a grant from the Nuffield Foundation.

COAGULATION OF PRIMATE BLOOD BY RUSSELL'S VIPER VENOM

By CHRISTINE HAWKEY and C. SYMONS
Nuffield Institute of Comparative Medicine, The Zoological Society of London

IN a comparative investigation of haemostatic mechanisms in captive wild animals, it has been found that the clotting system of non-human Anthropoidea is essentially similar to that of normal human beings. There is, however, one respect in which non-human primate blood differs from that of all other mammals so far investigated, namely, in the reaction with venom from *Vipera russelli*. This preliminary communication reports delayed clotting time in non-human primates with the Russell's viper venom (RVV) associated with normal prothrombin times. No previous reports of species differences in reaction to RVV have been found.

The coagulant activity of RVV is due to an esterase in the venom, which splits plasma factor X to form an active derivative[1–3]. This activated factor X, which is not neutralized by anti-venom, brings about rapid conversion of prothrombin to thrombin in the presence of phospholipid, factor V and calcium ions. Its action is independent of the presence of factors VII, VIII, IX, XI and XII. In order to mask the effect of variable amounts of phospholipid of platelet or alimentary origin, an optimum amount of cephalin or lecithin is included in laboratory tests with RVV. A mixture containing equal volumes of normal citrated human plasma, RVV('Stypven', Burroughs Wellcome) in 0·25 per cent ovolecithin and M/40 calcium chloride gives a clotting time of between 8 and 10 sec at 37° C. Reduction of the concentration of prothrombin, or of factors V or X, results in prolongation of this time.

Venous blood was collected into 1/10 volumes of 3·8 per cent trisodium citrate from ten monkeys approximately 15 min after tranquillizing with an intramuscular injection of 'Phencyclidine' (2 mg/kg). Platelet-poor plasma was either tested immediately or stored in polystyrene containers at −35° C until tested. Table 1 shows RVV clotting times and prothrombin times[4]. In all monkeys the RVV clotting time was greater than in humans, whereas in all other mammals tested the RVV clotting time was less than 10 sec. Prothrombin times

measured for the same plasma samples were all within the normal human range, indicating levels of prothrombin and of factors V, VII and X comparable with those in humans. This was confirmed by two-stage prothrombin tests[5] and assays of factors V (ref. 6), VII (ref. 7) and X (ref. 8), all of which gave normal results. Monkeys belonging to the family Cercopithecidae show the most marked prolongation with RVV. Fig. 1 indicates the relationship between prothrombin time and RVV clotting time in a variety of animals, demonstrating the prolongation of RVV clotting time in non-human primates.

As prolongation of the RVV clotting time cannot be explained by deficiencies of clotting factors, the possibility was considered that monkey blood contains a venom inhibitor. The presence of such an inhibitor was tested for as follows. Human serum, or serum from *Cercopithecus ascaneus schmidti*, was incubated with equal volumes of RVV in ovolecithin at 37° C. At intervals, a sub-sample of this mixture was added to normal human substrate plasma and the clotting time recorded after recalcification. The results given in Table 2 show that the ability of RVV to clot human plasma is not impaired by incubation with monkey serum, thus excluding the presence of an inhibitor active *in vitro*.

The results of this experiment also indicate that RVV reacts normally with monkey factor X, producing activated factor X which will rapidly convert human prothrombin to thrombin. Substitution of monkey plasma for human substrate plasma in the second stage of the test, however, results in prolongation of the clotting times (Table 2). This suggests that the reaction between RVV-activated factor X and monkey prothrombin and/or factor V is the limiting feature. Further experiments with purified clotting factors are required to confirm this.

Human	Monkey	17	18 5	20

The fact that all other coagulation tests carried out on the monkeys under discussion have given results within normal human limits shows that the coagulation system—an important part of the haemostatic mechanism—is well developed in primates. The reduced reaction with RVV, which has been demonstrated *in vitro*, may also be of significance *in vivo* and, as snakes are natural enemies of monkeys, may have evolved as a result of natural selection.

This work was supported by a grant from the British Heart Foundation. We thank O. Graham-Jones for collection of blood samples and G. F. Nevill for technical assistance.

NEWS AND VIEWS

Microbiology in the Queen's University of Belfast: Prof. K. B. Fraser

DR. K. B. FRASER has been appointed to the chair of microbiology in the Queen's University of Belfast, in succession to Prof. G. Dick (*Nature*, 207, 916; 1965). Dr. Fraser graduated M.B., Ch.B. in 1940 in the University of Aberdeen, and after a distinguished war record, including the award of the Military Cross, he returned in 1946 to Aberdeen where he took up a career in microbiology, eventually becoming a senior lecturer in the Department of Bacteriology. In 1961 he moved to Glasgow and joined the staff of the newly built Institute of Virology as a senior lecturer in virology and an honorary consultant virologist, and has remained in this post until his present appointment. Dr. Fraser's interest in virology began in 1951 when he spent a year working with Sir MacFarlane Burnet in Melbourne. He was responsible with Sir MacFarlane for much of the early work on the genetic recombination of influenza virus, and on his return he continued with his well-known study on virus virulence factors. His interest in genetics was continued during a further period in 1959 as a Research Fellow with Prof. Pontecorvo in Glasgow. Dr. Fraser's other main interest is in the field of immunology and he has been a pioneer in the applications of immunofluorescent techniques in experimental virology. During the past few years in the Institute of Virology in Glasgow, Dr. Fraser and his group have been working on incomplete growth cycles of myxoviruses, and on early stages of polyoma virus growth and transformation. In addition to his distinguished research, Dr. Fraser's ability as a teacher is well known to both

medical and science students in Aberdeen and Glasgow, and also to postgraduates who have attended the recent courses in basic virology at Glasgow.

Director of the Forest Products Research Laboratory: Mr. J. Bryan

MR. J. BRYAN, director of the Forest Products Research Laboratory of the Ministry of Technology, retired from the public service on December 31, 1965. With the exception of a short period with Dorman Long, Ltd., early in his career, he devoted the whole of his working life to the study of timber and the service of the Forest Products Research Laboratory, which he joined virtually at its inception in 1926. He formed and led the section working on wood preservation and later became head of the Timber Mechanics Section. He took charge of all engineering investigation in the Laboratory in 1945 and was appointed assistant director in 1954 and director in 1962. An engineer by training and inclination, with a keen interest in natural products and processes, he was well fitted to assist in the transformation of timber from a craft to an engineering material and the establishment of a scientific basis for wood technology. During his period of service with the Laboratory he saw great advances on both these fronts and he saw the Laboratory develop into a leading world authority on timber and its use. His career spanned most of the life to date of the Forestry Commission, with which he worked in close co-operation, especially when its plantations began to reach the age when timber properties could be tested. He was for some years chairman of the joint Committee on Research into Home-Grown Timbers of the Department of Scientific and Industrial Research and the Forestry Commission.

Mr. T. A. Oxley

MR. T. A. OXLEY has been appointed director of the Ministry's Forest Products Research Laboratory, Princes Risborough, in succession to Mr. Bryan. The appointment took effect from March 1. Mr. Oxley was born in Hampstead, where he attended the Haberdashers Aske's School, and graduated with honours from the Imperial College of Science and Technology in 1933. After spending 2 years on postgraduate research, he worked for 3 years as a demonstrator at Imperial College. He then joined a group in the Department of Zoology at Imperial College, investigating, as a grain-specialist, pest infestation of stored products. This group later formed the Pest Infestation Laboratory of the former Department of Scientific and Industrial Research, where Mr. Oxley became head of the biology section and later of the grain-storage section. He was appointed assistant director of the Tropical Products Institute in 1959. For the past 5 years Mr. Oxley has been a deputy commissioner, scientific and engineering directorate, of the Civil Service Commission.

Council for National Academic Awards: Recognized Degree Courses

THE first report of the Council for National Academic Awards covers the year ended September 30, 1965, and records the establishment of three Boards of Studies for Arts and Social Studies, Science and Technology, and Research Degrees, as well as of eighteen Subject Boards (Pp. 33. *Recognised Degree Courses*. List No. 2. Pp. 6. London: Council for National Academic Awards, 1965). The Council considered 67 courses in business studies, science and technology proposed by Colleges to lead to the Council's degrees; arrangements have been made to award the Council's degrees to holders of either the Diploma in Technology or Membership of the College of Technologists who wish to convert their awards. At the beginning of the 1965–66 academic year, 4,073 students were enrolled in 89 courses leading to the Council's degrees, including 129 first-year students in five courses leading to a B.A. degree in business studies. Of fifty-seven courses in science and technology considered by the Council, seventeen were approved to start in 1965 and a further seven to start in 1965 or 1966 subject to satisfaction on outstanding points; thirty-three were rejected. Five out of ten courses in business studies were approved to start in 1965; two were approved to start in 1966 subject to satisfaction on several points; three were rejected. Of the 4,073 students enrolled, 1,052 were in mechanical and production engineering, 978 in electrical and electronic engineering, 493 in civil engineering, 410 in chemistry, chemical technology and industrial chemistry, 359 in physics and physical electronics, and 220 in aeronautical engineering. Appendixes give the membership of the various Boards of Studies.

Sixth-form Teaching

THE Schools Council is in the unenviable position of having to foster change in the British educational system without treading on the corns of its sponsors—principally the local authorities responsible for education systems, organizations of professional teachers and the Department of Education and Science. In the circumstances it is inevitable that it should spend a good deal of its energy flying kites, talking of innovation and then waiting to see whether the result is delight or revolution. This seems to have been the spirit in which the Schools Council organized a conference in Nottingham a year ago to parade before a small group of teachers some recent suggestions as to how the pattern of science teaching in the sixth forms of British secondary schools may, in the near future, change. A record of this conference has now been published (*Science in the Sixth Form*, H.M.S.O., 4*s*. 6*d*.).

Outside the United Kingdom it may seem strange that British schools should regard as daring an experiment in which some of the material now taught to senior secondary pupils under the separate labels of physics and chemistry should be combined in a single course called physical science. Indeed, the proposal is only meaningful in the context of the British sixth form, where most students aiming at university or higher education follow courses in three specialized subjects, and where schools are urged, sometimes vainly, to devote a third of the time available to broader pursuits (including physical education). The most compelling argument for physical science, advanced at Nottingham, is that such a course would make it possible for those going on to science departments at universities to know something of the biological and the physical sciences, and to learn some mathematics as well. At present it is all too common that students intending to go on to university are required to choose, at sixteen or so, on the particular discipline in which they intend to graduate 5 years later, and that they should promptly direct their studies to that end. A course in physical science would make it possible to postpone this choice for 2 years and—giddy thought—might even allow some intending scientists to read a little history.

Prospects for Change

A group of a dozen schools is likely to try out such a course in the years immediately ahead. The value of the experiment will obviously depend on whether British universities are willing to give it a fair wind. Nothing said at the Nottingham conference can be used to predict how things will go, but when the results of the first experiment are available for study, the universities are bound to worry a great deal, in part legitimately, before deciding what their attitude will be. It would be a great, though uncovenanted, benefit if one consequence were the fuller involvement of British universities in the creative evolution of the school curriculum.

A more radical proposal given an airing at the Nottingham conference was for a pattern of sixth-form study

made up from 'minor' as well as 'major' courses. On paper, a minor course would take half the time of a major course. Theoretically, a student could choose between a concentrated pattern of studies of the kind now common and a much broader and more liberal education. The Schools Council is obviously keen on the concept, though it is bound to be a long time before the universities and the schools are thoroughly convinced. In the hope of showing that its proposals are practical, the Schools Council is working hard to design teaching time-tables in which major and minor courses are intertwined. In time, no doubt, there will be practical experiments in schools. Success could bring a new pattern of sixth-form science teaching within a decade. Certainly the talk that there is bound to be of this proposal will sharpen discussion of the four-year university course.

Essays on Humanity

IN his *Two Essays on Humanity*, K. W. Monsarrat is concerned first with "Man's Thoughts" and then with "Man's Health" (Pp. 19. Liverpool: Henry Young and Sons, 1965). In his first essay he elaborates the thesis that the most precious of all man's neural abilities is the ability to form validity judgments and to exert his powers accordingly. He emphasizes the need for recognition that the word 'mind' represents an abstract idea of the individual's thought-producing activity by that part of his cell-structure which the microscopist terms his brain-cortex, and refers to the clinical evidence that changes in the blood content as the blood-stream passes through glandular structures may affect the production of thought. In the second essay, he criticizes the development and organization of the health service, arguing that a really comprehensive scheme has been prevented by the party structure of Parliament assisted by the short-sightedness of the British Medical Association, which, like Parliament itself, twice failed to grasp the opportunity, originally presented by the report of the Dawson Committee in 1920. In consequence, he maintains that the family doctor has been forced to choose between reducing the standard of his care of his patients, submitting to financial straits which mean relative poverty, abandoning his profession or emigrating.

British Acoustical Society

THE Acoustics Groups of the Institute of Physics and the Physical Society and the Society of Acoustic Technology in the United Kingdom have spawned a new society—the British Acoustical Society—which is intended to cover the "rapid growth of interest and discovery in the various branches of acoustics in Britain". The new society hopes to bring some simplification to a field of study in which a number of separate societies and sub-groups have sprung up in recent years. It will be concerned with "all aspects of sound, hearing and vibration", and will be engaged in problems of great public interest such as aircraft and traffic noise, the design of concert halls and the industrial uses of sound, including ultrasonics. The planning of the new society has been done by a committee under Sir Gordon Sutherland as chairman, and the new society will be managed provisionally by a council with Dr. A. J. King as chairman and Prof. E. J. Richards as vice-chairman. There is to be an inaugural meeting during May 5–6 at the Department of Physics of the Imperial College of Science and Technology, London, S.W.7. Further information can be obtained from Dr. R. W. B. Stephens at that address.

Chemistry and Metabolism of Lactic Acids

Chemistry and Metabolism of L- *and* D-*Lactic Acids* contains a series of papers presented at a conference held in November 1964 (*Ann. N.Y. Acad. Sci.*, 119, Article 3. By N. R. Alpert and 45 other authors. Pp. 851–1165. New York: New York Academy of Sciences, 1965. 6 dollars). The objects of the conference, as stated by the co-chairmen, were to demonstrate the need to use specific isomers in metabolic studies rather than the D,L-mixtures frequently used, and to bring together present knowledge on lactic acid. The first of these objectives is worthwhile, since investigations with stereospecific enzymes have shown that the information gained by using racemic substrates is often misleading, and many of the papers in this volume amply show that a great deal more information can be obtained using the individual isomers of lactic acid. The large amounts of information available on some aspects of the subject make the second objective difficult to attain: the material available on the lactic dehydrogenases could in itself fill a volume. The volume opens with a paper on the chemistry of lactic acid, followed by a series of papers dealing with specific enzymes concerned in the metabolism of the lactic acid isomers and other hydroxy acids. The study of the metabolism of the lactic isomers then proceeds from these specific enzymes to metabolic pathways in micro-organisms, tissue preparations, isolated organs and the intact animal. The final section of the volume consists of papers on the medical aspects of lactic acid metabolism. This section contains a paper on the metabolism of the lactic acid isomers in human brain in both normal and mental patients, followed by four papers on lactic acid levels in the blood during acidosis, shock, neonatal life and hyperventilation. The volume represents a useful survey of the various aspects of lactic acid chemistry and metabolism, in which condensation of the subject-matter due to space limitations is largely offset by lists of references at the end of each paper. As such it can be recommended to anyone interested in the important aspects of this field, and also to anyone tempted to use racemic mixtures in enzymatic or metabolic investigations.

Occurrence of *Rana ridibunda* in a Hot Spring near Edremit (Turkey)

ATILLA ÖZALPAN, of the Department of General Zoology, University of Istanbul, has written to the Editor as follows: "It is unusual to find vertebrate species in hot springs. For this reason, we have found it worth-while to report the occurrence of *Rana ridibunda* in a hot spring near Edremit (Balikesir, Turkey). The temperatures of different parts of the hot spring are shown in Fig. 1.

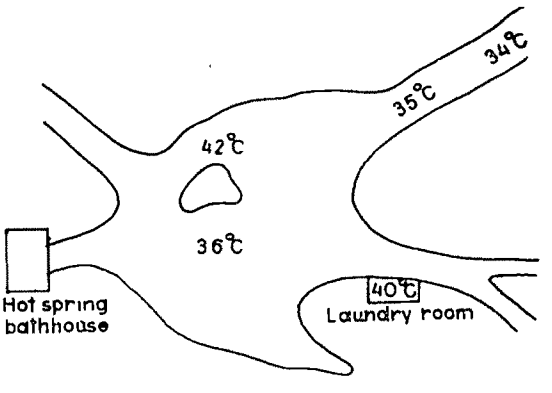

Fig. 1. The hot spring (Derman) near Edremit

"On April 23, 1965, many small metamorphosed individuals and tadpoles of different sizes were collected from the hot spring. The larvae and the frogs appeared to have no particular preference for a special temperature in the hot spring. They were found in its coldest and hottest regions. It seems that the frogs are adapted not only to the temperature of the water but also to its salinity. The physiological basis of this phenomenon is being worked out in our laboratory and will be published elsewhere."

University News: Bradford Institute of Technology

DR. D. W. MATHIESON, reader in pharmaceutical chemistry in the University of London, has been appointed professor of pharmaceutical chemistry.

Strathclyde

DR. W. C. BOWMAN, reader in pharmacology in the School of Pharmacy, University of London, has been appointed professor of experimental pharmacology in the University of Strathclyde. Dr. Bowman's major research interest is in the mechanism of action of drugs which interfere with synaptic and neuro-effector transmission.

Sheffield

PROF. G. J. HOIJTINK, professor of chemistry in the University of Amsterdam, has been appointed to the chair of physical chemistry. Prof. R. McWeeny, professor of theoretical chemistry in the University of Keele, has been appointed to the chair of theoretical chemistry.

Swansea

MR. J. OLIVER, senior lecturer in the Department of Geography, has been appointed to the newly established second chair of geography in the University College of Swansea.

Awards and Appointments

DR. PEYTON ROUS has received the Paul Ehrlich and Ludwig Darmstaedter Prize, which is the highest medical award of West Germany.

PROF. G. PUPPI has been elected chairman of the CERN Scientific Policy Committee, in succession to Prof. L. Leprince-Ringuet.

DR. D. H. WHIFFEN was appointed superintendent of the Division of Molecular Science at the National Physical Laboratory, Teddington, Middlesex, as from April 1.

H. B. STEWART, JUN., formerly chief oceanographer of the Coast and Geodetic Survey, has been appointed head of the New Institute for Oceanography of the U.S. Environmental Science Services Administration

Announcements

THE U.S. National Academy of Sciences and the Academy of the Socialist Republic of Romania have announced a three-year exchange programme, providing for visits of up to one year by individual scientists of the two countries to lecture and to conduct research. The new programme is the third to go into effect this year between the U.S. Academy and one of its sister institutions in Eastern Europe.

A SYMPOSIUM on "Terpenoids in Plants", organized by the Phytochemical Group, will be held in the University College of Wales, Aberystwyth, during April 12–14. Further information can be obtained from Mr. A. H. Williams, Research Station, Long Ashton, Bristol.

A ONE-DAY symposium on "The Environmental Stability of Low-voltage Contacts" will be held at the Luton College of Technology on April 13. Further information can be obtained from Dr. M. G. Parker, Luton College of Technology, Park Square, Luton, Bedfordshire.

THE second international conference on "Electron and Ion Beams" will be held in New York during April 17–20. Further information can be obtained from the Secretary, Institute of Metals Division, Metallurgical Society of A.I.M.E., 345 East 47th Street, New York.

A JOINT meeting of the Microchemical Methods Group and the Scottish Section of the Society for Analytical Chemistry will be held in the University of Edinburgh during April 15–17. Further information can be obtained from the Society for Analytical Chemistry, 14 Belgrave Square, London, S.W.1.

A ONE-DAY colloquium on "Winning of Chemicals from Flames" will be held by the British Section of the Combustion Institute in the University of Sheffield on April 15. Further information can be obtained from Prof. W. G. Parker, Department of Chemistry, College of Advanced Technology, Birmingham 4.

A SEMINAR on "The Dynamic Role of Molecular Constituents in Plant–Parasite Interaction", sponsored jointly under the United States–Japan Co-operative Science Program by the National Science Foundation and the Japanese Society for Promotion of Science, will be held in Gamagori during May 15–21. Further information can be obtained from Dr. C. J. Mirocha, Department of Plant Pathology and Physiology, University of Minnesota, St. Paul.

Central eclipse at local apparent noon	9h 51m	
Central eclipse ends	11h 23m	
Eclipse ends	12h 26m	

SCIENTIFIC RESEARCH IN INDIA

THE Survey and Planning of Scientific Research Unit of the Council of Scientific and Industrial Research, New Delhi, has issued a survey of scientific research in Indian universities, based primarily on the annual reports of some twenty-five universities, and covering twelve scientific subjects*. Forty-eight universities have scientific departments, and nine sent reports for the full 10 years (1952–62); some of the new universities did not send annual reports. The survey gives the total number of papers published by the university departments each year since 1952–63, and the distribution by subject and by periodicals, with statistics of authors. In the period covered, the number of Indian universities has grown from twenty, with 108,722 students in science faculties, to fifty-five, with 1,386,374 in science faculties.

In agriculture, Allahabad, Andhra, Annamalai and Calcutta appear to have active research departments; at Calcutta and Banaras most of the emphasis is on agricultural botany, and at Annamalai on pathology; animal husbandry and veterinary science are receiving little attention. Most of the universities except Aligarh, Jabalpur, Jadavpur, Mysore, Saugar and Karnatak are active in botanical research, notably at Allahabad, in the physiology and ecology of angiosperms and plant pathology due to fungi. The morphology of angiosperms is being studied at Andhra, the physiology and ecology of angiosperms at Annamalai, cytogenics of angiosperms and other groups at Calcutta, morphology and physiology of angiosperms at Delhi and Utkal, and plant pathology due to fungi at Madras. In chemistry, 589 papers came from Andhra, 438 from Calcutta, 374 from Delhi, 360 from Lucknow, 265 from Banaras, 236 from Jadavpur, 234 from Utkal and 216 from Madras. In Delhi, Lucknow, Calcutta, Banaras, Annamalai and Poona, the emphasis was mainly on organic chemistry; at Allahabad on physical chemistry; inorganic work came chiefly from Allahabad, Andhra, Banaras, Jadavpur and Utkal. Only Calcutta was concerned with research in industrial chemistry and work on analytical chemistry was mostly insignificant. In engineering, 80 per cent of the papers published were in chemical engineering and only in Banaras was there any research in metallurgy.

There is considerable research activity in geology at Andhra, Calcutta, Jadavpur and Lucknow, while in mathematics the contribution has come mainly from Lucknow, Calcutta, Delhi and Banaras. Out of 95 papers from Banaras, 63 were published in 1961–62, the theory of numbers and theory of functions accounting for 60 per cent of the total. Those from Banaras were concerned mainly with relativity and theory of functions; from Lucknow, with algebra, theory of functions and mechanics; from Delhi, with geometry and mechanics; from Calcutta, with algebra and geometry; and from Allahabad, with the theory of functions. Research in the medical sciences was most active at Lucknow, followed by Andhra, Bombay, Delhi, Nagpur and Poona. Medicine and pharmacology, with some pathology and physiology (Lucknow), physiology and medicine (Bombay), physiology (including biophysics and biochemistry) (Calcutta), and pathology, anatomy, medicine and gynaecology (Andhra) were the chief fields. Only at Andhra, Banaras and Panjab was effective research in progress in pharmacology, about 90 per cent of papers from Andhra and 70 per cent from Banaras being in chemotherapy.

Most universities were consistently active in physics, especially nuclear physics (Bombay and Delhi); theoretical physics (Madras, Annamalai and Delhi); spectroscopy (Andhra); electronics (Andhra and Calcutta); microwaves and acoustics (Andhra); crystallography, biophysics and mechanics (Madras). Bombay and Calcutta have published a few papers on cosmic rays. Calcutta, Baroda, Bombay and Poona, with Karnatak (since 1958), have published most of the research papers in statistics, largely on the design of experiments, theory of inference and descriptive statistics. Only at Utkal, Kerala and Sri Venkateswara has there been any research in veterinary science, but Lucknow, Madras, Andhra, Baroda, Delhi, Allahabad, Annamalai and Sri Venkateswara have active research departments in zoology. Cytogenetics appears to be neglected except at Allahabad. Of the Council's total research grants to universities of 8·8 million rupees in 1958–65, 45 per cent was for chemical research, 22 per cent for physical research and 11 per cent for biological research.

* India: Council of Scientific and Industrial Research. Survey Report No. 6: *Scientific Research in Indian Universities*. By U. Sen, A. Rahman, S. P. Gupta, A. K. Roy, S. Malik, S. H. M. Husaini, S. Das Gupta and Y. K. Agarwal. (New Delhi: Council of Scientific and Industrial Research, 1965.)

FUNCTIONAL ARCHAEOLOGY

THE value to the prehistorian of experimentation with archaeological material has long been recognized. The list of materials submitted to testing for methods of production and for possible functions is a long one, ranging from the working of flint and stone to the firing of Romano-British pottery in reconstructed kilns, and this article draws attention to two recent experiments in functional archaeology.

Among the first archaeologists to consider the possibilities of this approach was Sir John Evans, who compared his prehistoric flintwork with that produced by his nineteenth-century contemporaries at Brandon in Norfolk and in other countries as well. In Scandinavia, Jorgensen and Steensberg have in recent years directed experiments with flint axes to see how efficiently these could fell trees, and the next stages in primitive cultivation, burning and sowing of seed, have also not been neglected. In Britain, ploughing experiments with reconstructed Danish ards have recently been carried out, and these may be of real assistance in interpreting the traces of ploughing recovered from such sites as Gwithian in Cornwall. The Council for British Archaeology has also carried out experimental work on storage pits to see how efficiently these basketry-lined pits preserved grain. In Ireland the cooking experiments on Bronze Age sites are quite well known, and seem to have been successful both in function and in the taste of the finished product. Many other experiments involving the reconstruction of larger-scale

monuments, defensive ramparts, standing stones and wattle-and-daub houses could be mentioned, but the present article emphasizes the experimental techniques involving the functions of actual or duplicated artefactual material. A considerable amount of experimental work has been carried out on the casting of copper and bronze products, and on the firing of Romano-British pottery, but these have been concerned mainly with production techniques, while it is the functional aspect that is particularly relevant at the moment. Recent work on this aspect has included the testing of the capabilities of sheet metal and leather shields to stand up to sword and spear blows, the determination of the range of musical notes obtainable from both Danish and Irish Bronze Age horns, the function of Upper Palaeolithic and early Mesolithic harpoon-heads, and, most recently, two papers in *Man* (65, 1965) which advance new interpretations of the function of well-known Palaeolithic artefacts. In one (No. 148) Dr. M. D. W. Jeffreys attempts to show that the handaxe, that characteristic tool of the widespread African Chelles-Acheul and European and western Asian Abbevillian and Acheulean industries, was not in fact a handaxe, but was a handbolt or missile. He defines a handaxe as an elongated tool with a pointed and a blunt end, bifacially worked with a cutting edge all the way around which shows no sign of wear. Because of the cutting edge, Jeffreys believes that such axes could not have been held in the hand, and he argues that these objects were hurled, the blunt end aimed at the quarry and thrown with the cutting edge horizontal to the ground. The weight distribution he thinks would cause the missile to revolve in such a way that the sharp-pointed end would move at great speed. In my opinion, experimental throwing of handaxes seems to disprove this theory; handaxes exhibit immense variation in their form, and many of the type with one pointed end have a rounded butt deliberately left unretouched, presumably to provide a safe grip. That different shapes and sizes of axes were designed for different functions seems without question, but it is incorrect to call all these tools handbolts.

The second paper (No. 143) is a contribution by Leon Underwood and is concerned with Upper Palaeolithic perforated batons. These, often decorated, have been interpreted in the past as leather-working tools, arrow straighteners, or generally as emblems of authority and ceremony. Underwood argues that these batons were used as spear-throwers on the basis of analogous forms in Eskimo throwers. The latter have a prepared grip and a nipple to engage the end of the spear shaft. On not a single Palaeolithic baton has the end survived sufficiently to provide the slightest hint of a nipple or hook, and apart from this hypothetical appendage, there is really no point of comparison between the batons and the Eskimo throwers other than the hole or holes. That such batons, if provided with hooks, would function as spear-throwers is not disputed, because Underwood has provided models to show this. But there are a few complete Palaeolithic batons, and these show no sign of the hook nor of a bound-on hook. In any case it would seem strange if the development of the baton as a spear-thrower, from Aurignacian times through the Magdalenian, did not become abruptly altered by the apparently quite rapid appearance of the true spear-thrower in mid-Magdalenian times; in fact, there is a high degree of consistency in baton development over some 15,000 years. Underwood has made a number of provocative statements in his paper; although some of these are improbable, his ingenuity may nevertheless stimulate further work of this experimental kind.

J. M. COLES

THE TEACHING OF PARASITOLOGY

PARASITOLOGY is taught in schools, in agricultural and biological departments of universities and technical colleges and in schools of medicine and veterinary medicine. Parasitologists are employed in a wide range of research establishments and many people trained in parasitology have found employment outside this field. The British Society for Parasitology felt that a meeting on the teaching of this subject would bring together those who taught and those who employed parasitologists and that all would profit from an informal discussion of common aims and problems. Accordingly, a colloquium was held at the Imperial College of Science and Technology, London, on January 10.

The form of the colloquium itself was an experiment as a large number of people were expected to attend and the usual formal meeting was quite unsuitable as a basis for the informal discussion which was envisaged. It was eventually decided that four speakers should briefly discuss particular topics of a general or controversial nature and that the participants should then divide up into small groups to discuss the papers and a list of topics prepared by the organizers. Each group was to be led by a rapporteur and at the end of the group discussions the participants would reassemble and listen to summaries from the rapporteurs and discuss them. In advance, each participant received a summary of the replies to a questionnaire which gave some idea of how much and what kind of parasitology was being taught in Great Britain. Questionnaires had been sent to biology or zoology departments of universities, schools of medicine and veterinary medicine and certain colleges of technology. Forty-one biology or zoology departments in universities were approached; thirty-five replied, and of these twenty-nine ran some sort of course in parasitology and twenty-three of these planned to expand their courses during the next 5 years. Eighteen of the twenty-two medical schools replied and twelve of these ran parasitology courses, three of which will be expanded. All six veterinary schools replied and four of these ran courses, one of which is to be expanded. Seventeen technical colleges were sent questionnaires and twelve replied; of these, nine ran courses and all planned some expansion. In all, fifty-four separate departments run eighty-three courses in parasitology each year and a considerable further expansion is envisaged. These courses are very varied and range from one or two lectures to postgraduate courses lasting a whole academic year. The content of the courses is also varied but, in general, the parasitology taught to the veterinary students is applied, while that taught to all other students ranges from wholly systematic to wholly experimental, although most courses cover all aspects of the subject to some extent. Other information obtained from the questionnaire dealt with the nature and content of parasitology courses and was intended to act as a stimulus for discussion.

Eighty-six people attended the colloquium, which opened under the chairmanship of Prof. B. G. Peters, who outlined the nature, aims and procedure of the meeting. Prof. W. E. Kershaw spoke in general terms about the teaching of parasitology and more particularly about the M.Sc. course at the University of Liverpool. The second speaker was Dr. H. D. Crofton, who discussed the different problems involved in teaching science and veterinary students. The latter, he said, regarded

any course as an interruption in the path of their chosen career and thought they could obtain most of the parasitology they needed from the publications of the pharmaceutical firms. The method of teaching different types of students should vary considerably, and scientists could benefit from an ecological approach. D. A. Denham spoke from the point of view of someone who had recently been taught parasitology. He criticized the tendency to teach this subject as an extension of a course on systematic zoology; in other words, parasites rather than parasitology. Nothing was more disheartening to a student than boxes of stained slides, and many must have been put off the subject by this approach. The parasites of parasitology, he said, were those who used this easy way of teaching. The last speaker was Dr. S. R. Smithers, who spoke as one working in a research establishment as a 'consumer' of parasitologists. Dr. Smithers argued that a parasitologist ought to be something else as well, an immunologist, a pathologist or a taxonomist, for example. Specialization ought to be something that came after an undergraduate career. An ideal situation would be one in which an undergraduate received instruction in a number of interlinked disciplines including parasitology.

The meeting then broke up into five groups in order to discuss the teaching of parasitology informally, and reassembled at the end of the day to summarize the findings.

The topics discussed and the views aired in the discussion groups were many and varied and it would be impossible to summarize them all in a short space. It was generally felt that something about parasites ought to be said at schools, but that there was no need for a separate course in parasitology. The use of parasites other than those in the standard text-books was desirable especially as many are easily obtained from animals used for dissections, whereas few schools have the facilities to show pupils the living parasites required by most syllabuses. Plant nematodes are a particularly good introduction to experimental parasitology as their use requires no licence. The teaching of undergraduates was discussed at length and the only common conclusion reached was that there are many ways of teaching parasitology and this variety cannot do anything but good for the subject.

It was felt that veterinary students required a course which was vocational in nature and that, unless they were being specifically trained for work in the tropics, parasites such as trypanosomes need only be mentioned in passing. During such a course a student should be introduced to the wider field of parasitology, but this should not be the main object of the course. Medical students receive very little training in parasitology and it was generally agreed that a short course is useful and even one lecture is better than none, but that long courses would serve no particular purpose. The requirements of science students are quite different from those of medical and veterinary students, and the various opinions expressed ranged between wide extremes. General agreement was reached that parasitology ought to be mentioned early on in an undergraduate course in order to stimulate interest in the subject. This need not take the form of specific lectures but could be incorporated into zoology or physiology courses. Parasitic examples could be used to illustrate a variety of biological principles, and the way in which this was done could encourage interested students to look further into the subject.

What was generally agreed was that a sound biological background was necessary before parasitology could be studied in depth. The general feeling was that formal courses in parasitology should be left until the final undergraduate or first postgraduate year, by which time the students would have covered the necessary background. The type of course offered to final year students varies considerably from university to university, and this variation provided the basis for further discussion. No single type of course could equally be applicable in all departments and it was felt that a student needed instruction not only on the parasites and their interactions with their hosts but also on the disciplines which impinge on parasitology. A number of courses run at present take the form of a review of the parasitic protozoa, platyhelminthes, nematodes and arthropods, with brief mention of their physiology, biochemistry and ecology. It was regretted that only too often a parasite is regarded as something in a taxonomic key rather than as a living organism. It was agreed that some systematics must be taught and the more that is covered in the pre-parasitology years the less needs to be done in the final year. Students of parasitology should be able to use keys, and some training in this was thought to be necessary, although no agreement as to the extent of such training could be reached. Some felt that emphasis on difficult but basic characters, such as the bursae of nematodes, would be preferable to a general coverage of a number of taxonomic points and others felt the reverse. What was agreed, however, was that there is, and always will be, a need for people who can identify parasites.

Considerable discussion ranged around other possible approaches to the teaching of parasitology, especially the experimental approach, although few participants actually had much experience of such courses. The main difficulty seemed to be a lack of possible experiments, but most people were willing and able to devise suitable exercises based on their own first-hand experience, so the difficulty is really one of communication. It was agreed that the British Society for Parasitology would provide a useful service if it collected together a number of tried experiments and exercises and distributed them to those involved in teaching. Individual projects undertaken by students were also thought to be useful in the teaching of the subject and difficulties which might arise could be overcome by the exchange of information.

Postgraduate courses were discussed by all the groups and the opinions expressed varied considerably. The general feeling was that such courses were useful but that they could easily become white elephants. The courses really needed were those which brought several disciplines together and were of a vocational nature. There seemed no point in beginning a postgraduate course simply to assimilate material pushed out of an undergraduate course, nor was there any point in such a course if it was merely an expansion of one given to undergraduates. The problem of financing students for such courses was raised and difficulties had been encountered. The general feeling was that the initiation of postgraduate courses should not be undertaken lightly but that well-planned courses of a high standard and of a vocational nature could contribute much to the field of parasitology.

Other aspects of the teaching of parasitology discussed included the merits of sandwich courses, which were regarded as being very useful and in some ways better than the usual undergraduate courses. The expansion of this type of teaching might have a considerable impact on the future of the subject. The training of technicians should be mainly vocational but it was felt that those hoping to work in the tropics should be taught some basic science and, in particular, the use of keys.

All the participants at the colloquium had the opportunity to learn and to preach, and most did both, so the meeting served its purpose. Among the concrete proposals which arose were suggestions that the British Society for Parasitology should consider collecting not only the experiments in parasitology already mentioned but also lists of teaching materials and teaching aids such as films and film strips. It remains to be seen whether or not this meeting will have any impact on the teaching of parasitology, but there is no doubt that the subject will continue to be taught and no pessimism was felt concerning the future employment of the students in these courses.

BIOGEOGRAPHY OF SOVIET ASIA

EXPLORATIONS of the vast territory extending from the Urals and the Caspian Sea to the Pacific Ocean date back more than a century and have been intensified in the recent decades, but their results are scattered in many regional publications, either botanical, or zoological, rarely both. Two recent books, each dealing with a little-known part of Soviet Asia, provide much more comprehensive biogeographical information than is reflected in their titles*.

Middle Asia is not a political, but a physico-geographical unit comprising southern Kazakhstan, Uzbekistan, Tadzhikistan, Turkmenia, north-eastern Iran, Northern Afghanistan and the Tian-Shan system. Kryzhanovsky's book, in its introductory chapters, provides a concise history of exploration in this region, summarizing the views of botanists and zoologists on the present state and the origins of its vegetation and fauna. Equally concise and clear accounts are given of the palaeogeography of the region from the Upper Cretaceous to the Quaternary, emphasizing its continuous and gradually increasing aridity, except in the geologically younger ranges of the Tian-Shan; the main thesis is that the Middle Asian arid landscapes are much more ancient than those of the northern Africa in the west and the Central Asia in the east; fluctuations of climate and violent orogenetic processes favoured radiating evolution within the region of predominantly xerophilous flora and fauna. The main chapters of the book are based on a thorough analysis of the insect fauna in relation to the distribution of genera and species both within the region and elsewhere. This is followed by descriptions of the populations of various landscape types—sand deserts, sandy plains, submontane ephemeral steppes, mountains, river valleys and cultivated lands. In each case the background conditions of existence of plants and animals are discussed in relation to their previous evolutionary history and the resulting extremely intricate pattern of strongly contrasting elements is made clear. The concluding chapters present broad views of the present composition of the terrestrial fauna (not of insects only) and of the main events leading to its formation; the significant conclusion is that Middle Asia should be regarded as the most ancient and important centre of origin of the desert fauna and flora of the northern hemisphere, a view advanced by some Russian biogeographers in the past and opposed by others, but greatly strengthened by the overwhelming evidence so masterfully presented by Kryzhanovsky.

The book by Kurentzov deals with another fascinating and relatively little-known area, the Soviet Far East. The author's own field-work there extended over many years and he adopted an attractive method of taking the reader over a variety of landscapes, from the lush deciduous forests in the southern valleys, where many subtropical plants and animals are found; forests of cedar harbouring the Amur tiger; oak forests on mountain slopes; conifer taiga still higher up, with the peculiar flora and fauna of bare outcrops; semi-arid lands of Dauria, etc. Vivid descriptions of landscapes and of their animal (mainly insect) population are given and the typical representatives of the fauna of each ecological type are illustrated. A competent analysis of the fauna and of its chequered history, in relation not only to the surrounding parts of Asia but also to North America, concludes the book.

A feature of both books, which is characteristic of the Soviet approach, is that they include detailed cartographic division of the areas in relation to their natural resources, thus combining scientific description with the potential planned development. The wealth of the factual material, condensed from extensive, mainly Russian, literature, makes both books outstanding as the sources of up-to-date knowledge of the two regions of Asia which are among the less known to western biogeographers.

* *The Composition and Origin of Terrestrial Fauna of Middle Asia*, by O. L. Kryzhanovsky (Moscow–Leningrad, 1965), 419 pp., 24 figs. *The Zoogeography of the Amur Region*, by A. I. Kurentzov (Moscow–Leningrad, 1965), 155 pp., 80 figs.

VIRUS NOMENCLATURE

IF it is accepted that viruses have characteristics that distinguish them from animals, plants and bacteria, it follows that their nomenclature cannot be ruled by any of the existing international codes of nomenclature. Taking this into consideration and recognizing the need for an internationally adopted system of virus nomenclature, the International Association of Microbiological Societies (IAMS) has taken initial steps to set up an International Committee of Nomenclature of Viruses (ICNV) to meet for the first time at the Eighth International Congress of Microbiology being held next July in Moscow. Affiliated societies of microbiology have been invited to appoint members to serve on the committee.

A provisional Committee of Nomenclature of Viruses (PCNV) appointed by the International Association of Microbiological Societies met in Paris and prepared a document containing recommendations to be considered by the main meeting in Moscow (*Ann. Inst. Pasteur*, 5, 625; 1965). In these recommendations the basis for a code of virus nomenclature is suggested. The main points of these recommendations can be summarized as follows: (1) Viruses of animals, plants and bacteria should be gathered into the single phylum *Vira*. (2) The phylum should be divided into sub-phyla, classes, orders, families, genera and species, these divisions being by necessity arbitrary and not equivalent to taxa of other phyla. (3) Genera should have Latin or Latinized Greek names ending in *virus*. Each genus is typified by a well-authenticated species to be deposited in international culture collections. (4) Each family should be named after a type genus to which the suffix *idae* is added. (5) The code should not include a law of priority. A list of *nomina conservanda* in which virus names in general use are maintained whenever possible is submitted for approval by the International Committee of Nomenclature of Viruses. (6) Taxa designated after personal names, anagrams, siglas, hybrids of names or nonsense names should not be acceptable. (7) New names to be adopted must be submitted to the International Committee of Nomenclature through its Judicial Commission.

The question of virus classification as opposed to virus nomenclature is not ruled by the code and it is open to virologists individually or in groups to put forward proposals in this respect. Making use of this privilege, the provisional Committee suggests a system of virus classification conforming to the principles laid down in the proposed code.

Four characters, namely (*a*) type of nucleic acid, (*b*) symmetry of the virion, (*c*) presence or absence of envelope and (*d*) dimensions, are adopted in this hierarchical order

to divide the phylum into sub-phyla, orders, classes, families and genera.

The recommendations of the provisional Committee of Nomenclature were recently presented for discussion at a well-attended meeting of the Virus Group of the Society for General Microbiology held in London. That the proposals received considerable criticism is perhaps not surprising in view of the strong and even emotional feelings usually generated by matters of taxonomy. Critics fell largely into three groups:

(*a*) Those who thought that at our present state of ignorance viruses cannot be classified on a rational basis and therefore no attempts should be made to devise a uniform system of nomenclature until more information becomes available.

(*b*) A more important group of speakers pointed out a number of inaccuracies of fact and interpretation contained in the proposals and criticized the choice and hierarchical arrangement of criteria adopted for the classification system.

(*c*) Last, but not least, a number of speakers objected to the use of Latin names and to the adoption of a classification based on a fixed set of characters arranged in an arbitrary hierarchy. This group, represented mainly by plant virologists but supported by some eminent animal virologists, offered as an alternative a system based on Adansonian principles in which viruses would be designated by vernacular trivial names followed by a cryptogram containing information available or not on a number of unweighted characters (Gibbs *et al.*, *Nature*, 209, 450; 1966).

It is difficult to imagine a system of virus nomenclature which will please all virologists, but it is hoped that discussions such as the one reported here will lead to proposals acceptable by a sizable majority.

H. G. PEREIRA

PROBABLE MODE OF LANDING OF *LUNA* 9

By PROF. T. GOLD

Center for Radiophysics and Space Research, Cornell University, Ithaca, New York

FROM the data available through the news media concerning *Luna* 9 one can make some guesses as to its mode of landing which are of interest in a discussion of the lunar surface that is implied. Apparently, the spacecraft consisted of two parts: a bus of about 1·5 tons and a 2-ft. diameter sphere of 220 lb. It would seem that the sphere had no propulsion or attitude control units aboard but was merely the container for the experimental equipment. The bus contained all the proximity radar, the propulsion and attitude control units and all the associated electronics required to achieve the soft landing; that is, the low velocity relative to the lunar surface. The sphere was separated from the bus when its propulsion and control function was over—that is, in the final free-fall period.

Such a technique has several advantages in simplicity over one where the entire vehicle lowers itself on to the surface to stand erect for the purpose of the experimentation and telemetry:

(1) *Cancellation of the horizontal component of velocity.* In the *Luna* 9 technique it will be permissible, and possibly even advantageous, for the sphere to approach the surface with a horizontal component of velocity several times larger than the vertical. The radar control of the landing thus avoids the necessity of high precision in the detection and cancellation of this component, which is one that must be more difficult to control than the vertical. One supposes, therefore, that experiments will have been carried out of dropping the sphere in various ways on a variety of surfaces to decide what the permissible tolerance in the two components of velocity would be. On most surfaces the horizontal components of velocity could be between five and ten times greater than the vertical for a given permissible amount of damage or a given value of peak deceleration. One has to suppose, therefore, that the tolerances on the landing mechanism of the bus were such as to leave the sphere finally at impact with five to ten times as much horizontal as vertical velocity. We have no knowledge what the total velocity was beyond the statement that it was 'several metres per second'.

(2) *Absence of attitude control.* No attitude control is required in the final phase of the descent when all the active manoeuvre of the bus is finished. The sphere can be separated in some arbitrary way to skip, bounce and roll over the surface and finally come to rest. Its internal weight distribution may be such as to favour the desired way up and the subsequent opening of its four petals will assure that no extremely skew position can be maintained. It is obviously very unlikely that the sphere would lie precisely upside-down when the petals open so that they would fail to erect it.

(3) *Freedom from sinkage.* Such a method of landing will have appeared attractive in view of the unknown strength of the lunar surface. The loading should clearly be greatly reduced by abandoning all heavy rocket and control equipment and relying on a comparatively light sphere of a diameter comparable perhaps to that of the bus. Secondly, a large horizontal velocity at the impact of the sphere would tend to make the initial impact one of skipping like a stone on water, rather than one in which digging-in could occur. For the velocity tolerances that would be likely, and for as flat an angle of approach as given by the ratio of horizontal to vertical velocity of between five and ten, such a sphere would indeed skip, even on water, and certainly on most suggested types of lunar surface. The place where the sphere finally comes to rest in this mode will not have suffered any impact loading, and the compaction will only be that appropriate to the lunar weight of the sphere, which it would seem is 40 lb.

If indeed this were the mode of landing of *Luna* 9 then it would be clear why no impact information has become available that reflects on the strength of the lunar surface. The sphere has no attitude control and probably no internal knowledge of attitude in its tumbling phase. Even if accelerations were available for telemetry no meaningful integration of the accelerations could be carried out beyond gaining some idea of the length of time for which the sphere skipped and rolled. The small effect on the vertical component of acceleration which any compressibility of the surface might have made can then obviously not be sorted out when there is no independent directional information available in that phase. It is thus probable that nothing more can be said than that a 2-ft. sphere pressing on the surface with a force of 40 lb. did not sink in more than a few inches. It is not quite clear what depth of sinkage the television pictures would have revealed but possibly as much as 6 in. would have gone unnoticed. The bearing pressure is then as low as 0·12 lb. per in.^{2}. Most proposed types of lunar surface material would maintain that.

The bus is not visible in the panoramic view obtained by *Luna* 9. The panorama unfortunately shows the near ground over less than half the way around only because the vehicle did not in fact erect itself sufficiently accurately.

The track that the sphere made on the surface would be likely to be from the direction of the bus and that track is thus also not on the available panorama. The other possibility, that the bus is not visible because it sank out of sight, but that on the other hand on the same surface the sphere left no visible track, is clearly most unlikely. The experimentation initially proposed then probably included a study of the visible track, and it was only the unfortunate angle in which the sphere came to rest that made this impossible.

The subsequent movement of Luna 9. It appears that between the picture-taking sequences, a movement occurred of unknown origin in which the camera position was changed by several inches. It was suggested in the Press that the experimenters involved had no knowledge of the origin of this movement and did not attribute it to any activity within the vehicle.

Earthquakes are clearly outside the range of reasonable explanations since a degree of such activity would be required that would have shown up in other ways.

On any dry, terrestrial ground, and in the absence of wind, it would seem very improbable that an object after coming to rest would make significant movements in a period of days. The observation must thus be taken to be a very significant one that implies properties of the lunar surface quite unlike those of terrestrial surfaces.

In whatever position the vehicle came to rest and whatever stresses, such as by spring-loaded panels, were then in effect, it would be necessary to discover some process with a time constant in the range of hours, to allow the movement to be triggered off. The immediate dynamical time constants of the settling would be in the neighbourhood of seconds only. Plastic time constants in dry rock are many orders of magnitude too long. Thermal heating and cooling could have the right time constants, but the displacements resulting are so small that one would need to suppose the vehicle to be extremely delicately poised for such effects to trigger off a substantial movement.

It is thus quite a puzzle to discover some effect that would have been going on for a period of hours after the landing which, when it reached a certain stage, allowed a sudden resettling of the vehicle. Time constants of the same nature as those in an hour-glass may provide an explanation. If the material of the lunar ground were composed of small rock particles, slightly adhering to each other, it would be possible for there to be a lot of sub-surface hollow spaces. In particular, many small secondary impacts at rifle bullet speeds would make long tunnels at all angles through such a material. The structure that results would be the statistical equilibrium between the compacting effects of some types of impact and the tunnel-digging effects of others. On such a surface it would then not be too unlikely for the added weight of the vehicle to result in many little slides and collapses in internal cavities, which gradually reduce the strength of the ground and eventually let it settle. The time constants, as in an hour-glass, would be those of the dynamical time constants of falling grains but multiplied by the number of grains that had to fall in sequence to produce the effect.

While this explanation can be taken as a suggestion only, the fact that the ground tends to give way after some period of time under an additional load has probably to be taken seriously.

SIGNIFICANCE OF INCLUSIONS IN CARBONACEOUS METEORITES

THE possibility has frequently been suggested and discussed that all meteorites which have become available for observation have originated from the same parent body, or from a comparable set of parent bodies, of asteroid dimensions. Such a theory is supported by hitherto observed instances of interbrecciations between: siderite–pallasite; siderite–mesosiderite; siderite–chondrite; siderite–achondrite; mesosiderite–chondrite; mesosiderite–achondrite; chondrite–achondrite (for a summary see refs. 1 and 2).

That such a common origin exists has not yet been proved through actually observed associations of those meteorites which could be included in the 'main carbon-rich groups', with more than 0·2 per cent carbon (namely, (*A*) carbonaceous chondrites; (*B*) ureilites; (*C*) enstatite chondrites).

The thirty or so carbonaceous chondrites which have so far been recorded have been sub-divided by Wiik[3] into three types; the carbon + water + sulphur ranging between 24 and 30 per cent for 'type I'; 12 and 24 per cent for 'type II'; 3 and 12 per cent for 'type III'. Recent investigations have shown[4] that 'type I' stones consist of more than 90 per cent low-temperature ground mass of hydrated silicates and carbonaceous matter, of grain-size less than 1μ, in which are embedded globular or rounded particles, varying in diameter from 5 to 50μ, of magnetite, glass, olivine, troilite and other high-temperature minerals. I have interpreted[4,5] these to be 'microchondri', that is, solidified 'fog' particles from an incandescent cloud, as often they reveal exsolution cores. In the 'type II' stones, the ground mass is reduced to about 60 per cent and larger chondrules, that is, 'raindrops', are present in addition to the 'microchondri'. Most of these are, however, of the 'bunch of grapes' type, and still reveal the original microchondrules. These apparently became compacted in a viscous or sticky state. Within 'type III' stones the ground mass is reduced to about 35 per cent, and the majority of the chondrules are 'fully coalesced'; the latter stones grade into the non-carbonaceous chondrites. The three hitherto known ureilites contain between 0·5 and 1 per cent carbon, and they consist of what appear to be squashed single crystals or granular aggregates (possibly of 'microchondrules') of silicates, with concentrations of carbonaceous matter and diamonds along the grain boundaries. The ten enstatite chondrites contain 3–10 per cent carbon + water + sulphur, and, roughly speaking, have a petrographical structure similar to the 'type III' carbonaceous stones or the ordinary chondrites. More detailed descriptions of the carbon-rich groups of meteorites are to be found elsewhere[2,4,6,7].

This article describes some recently observed examples of inhomogeneities, inclusions and interbrecciation, in meteoritic materials of which at least one sample belongs to the foregoing 'carbon-rich' groups.

Inclusions

(1) *Orgueil*

Inclusion A. In the course of preparation of material for analytical work during 1962, I carefully separated some 3 g of the stone, obtained from a 20-g crust-less fragment from the Museum in Paris. An unusually hard, angular inclusion was found, which on analysis revealed a rather higher percentage of troilite plates and magnetite microchondrules than was present in the rest of the stone; however, the petrographical structure remained within the range of the 'type I' stones. An essentially similar type of angular inclusion was observed in a thin section of the Orgueil meteorite[8].

Inclusion B. I observed in a thin section of a rough-surfaces specimen of the Orgueil material from the Paris Museum an inclusion of about 1·5 × 1·0 mm cross-section. This had an approximately globular habit (in fact, in outline, it had the shape of a jug) and in cross-section appeared to consist of some eight 'bunch-of-grapes'-type

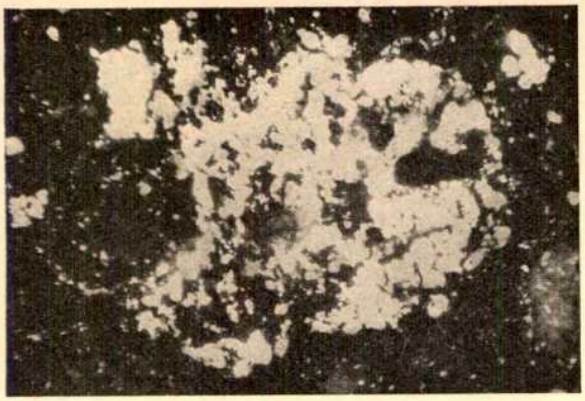

Fig. 1. Group of chondrules forming a small inclusion of 'type II' carbonaceous chondrite, within a thin section of Orgueil from the Museum of Paris. The two smaller chondrules on the lower left-hand side of the microphotograph reveal concentrical zoning of transparent (glass and crystalline silicate) and opaque (magnetite, troilite and nickel-iron) microchondrules. These rather rare features, however, were also observed by me in the 'type II' Cold Bokkeveldt, and the 'type III' Vigarano, and Mokoia. Ordinary light (×*c.* 45)

chondrules, and a larger coalescent mass of troilite within the largest of them (Fig. 1). The individual microchondrules were magnetite, troilite, glass and single crystal grains of a material as yet unidentified, but which appeared somewhat corroded and displayed a birefringence similar to that of olivine. The chondrule assemblage within the inclusion was comparable with that of 'type II' stones, in which similar groups of chondrules of up to 10 mm cross-section frequently appear, without much ground mass.

Inclusion C. In the course of dissecting a sample (see inclusion *A*), a hard, grey fragment, weighing 0·13 g, was obtained which, so far as could be deduced from the small quantity of substance available, closely resembled the pidgeonite chondrites—this was so both from the point of view of chemical composition (carbon, 0·17 per cent; sulphur, 2·26 per cent; hydrogen, 0·05 per cent), mineral composition and petrographical structure. When a powdered sample of the inclusion was examined, iron-rich olivine and pidgeonite were found together with the usual opaque minerals, including some nickel–iron. These would seem to have originated from major chondri, but a smaller olivine chondrule with the rather unusual feature of a 50μ diameter gas inclusion was also observed (see ref. 7).

(2) *Mighei*

A perfectly angular inclusion of about 4 cm × 2·5 cm surface area was found in one of the 'type II' Mighei stones from the Moscow Museum. The fragment in question is considerably lighter than the main mass, and an investigation using a binocular microscope revealed a chondrule assemblage characteristic of 'type III' stones.

(3) *Sharps*

The examples described so far illustrate fragments of meteorites of lower volatiles and lower carbon contents, included in hosts of higher carbon content. In contrast, an approximately brick-shaped 'type I' fragment with well-defined straight boundaries was discovered by Dr. K. Fredriksson (Smithsonian Museum, Washington) in the Sharps meteorite. The meteorite is at present being studied in detail by Dr. Fredriksson, and so this account will be restricted to a few preliminary observations. Both the elemental composition and the petrographical structure of the host material appear to be transitional between 'type III' carbonaceous chondrites and pidgeonite chondrites. The elemental composition of the inclusion according to Dr. Fredriksson is: carbon, 5·9 per cent; sulphur, 2·5 per cent; water, 2·5 per cent—the percentage of carbon being rather greater, and the sulphur and hydrogen lower than the range of the 'type I' stones at present known. Owing to the oxidizing conditions indicated by the mineral assemblage of the stone (and carbonaceous chondrites in general), it is not surprising that a proportion of the sulphur is found to be in a relatively volatile state as the free element and as sulphates, whereas the bulk of the carbon is in a relatively non-volatile state as graphite, amorphous carbon and highly polymerized organic molecules, the hydrogen, of course, being volatile. For this reason, we would expect that any thermal metamorphism would have resulted in a depletion of sulphur and hydrogen without a comparable depletion in carbon; this proved to be the case for the inclusion in question. The high carbon-level suggests that the inclusion was, in its original state, a material even richer in carbon, hydrogen and sulphur than our presently known 'type I' stones. That the inclusion entered the host when the latter was still hot is clearly indicated by the bands of 'redistribution' brought about by distillation of the carbonaceous matter. Such 'redistributions' follow, in a concentrical fashion, the margins of the inclusion and even those of the minor host inclusions or protrusions within the inclusion (see Fig. 2). Such a phase of thermal metamorphism is also indicated by the rather markedly crystalline nature of the ground mass, and by certain strain

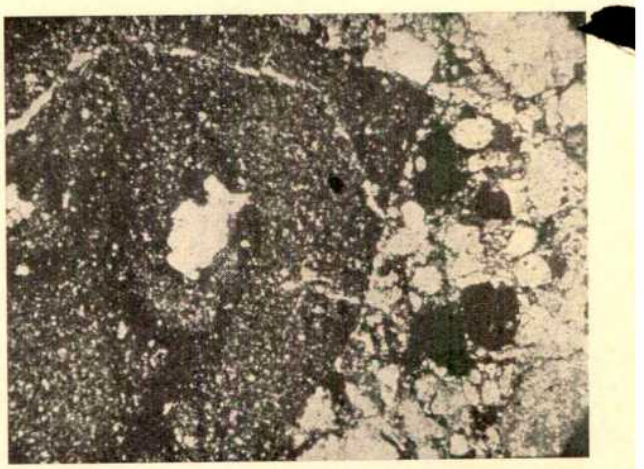

Fig. 2. Part of a 'type I' inclusion from a thin section of Sharps meteorites from the Smithsonian Museum, Washington. Note the marked change of statistical petrography between the inclusion and the host, and the dark carbon-rich zones which are approximately parallel to the margins, and to the margins of the two smaller inclusions of the host, within the inclusion proper. Ordinary light. (×*c.* 26)

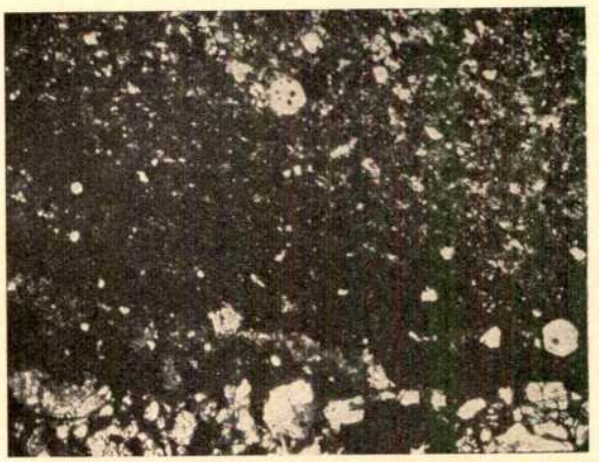

Fig. 3. Detail of an inclusion from Sharps meteorite. The boundary of the host runs along the base of the microphotograph. Note carbonaceous band parallel to the boundary, and also: (*A*) possibly strained glass cored microchondrule at the bottom right-hand side with a very low (about 0·05) diameter of core : diameter of microchondrule, ratio, which is characteristic of the 'type I' stones in general (ref. 4); (*B*) multicore olivine microchondrule, with troilite and nickel–iron cores, at top centre; (*C*) several glass and crystalline silicate microchondrules at top centre and left centre. Ordinary light. (×96)

anisotropy of some of the microchondrules of glassy appearance. On the other hand, microchondrules of unstrained glass, and cored microchondrules of crystalline silicate (most likely olivine), do exist (Fig. 3), which makes the similarity between the statistical petrography of 'type I' stones and the inclusion in question very close indeed.

(4) *Renazzo*

The features of the inclusion observed in the Sharps meteorite are essentially repeated, within a rather squashed inclusion, with some flow structures, in a thin section of Renazzo from the Smithsonian Museum, Washington (Figs. 4 and 5). The flow structure and inclusions of some chondri in this indicate a more intensive metamorphism, and this impression is strengthened by the more recrystallized nature of the ground mass (compare Figs. 2 and 3 with Figs. 4 and 5). The presence of individual glass and magnetite microchondrules is most significant (Fig. 6) as, in my experience, these are exclusively characteristic of 'type I' stones.

(5) *Cold Bokkeveldt*

The foregoing examples illustrate associations of meteorites within the chondrite–carbonaceous chondrite series. I found in one of the sections of Cold Bokkeveldt meteorite at the British Museum (Natural History) some angular material (perhaps squashed or fragmented large globular type chondrules) reminiscent of typical ureilite structure. An entire section from the same source, however, reveals an exclusively ureilite-type structure with large single crystal grains of clinopyroxene and globular patches of olivine, troilite and nickel–iron, obscured by carbonaceous matter, graphite and possibly diamonds along the boundaries. This structure is characteristic of the Goalpara ureilite, which can be classified as 'type I ureilite'. In the case of Novo Urey and Dyalpur, both the clinopyroxene and the higher melting olivine grains are coalesced into single crystals; these can be classified as 'type II ureilites', as they were formed at higher temperatures. A specimen of Cold Bokkeveldt exhibited in the Museum in Vienna is a breccia revealing numerous angular fragments of dark ureilite in the lighter matrix of the 'type II' stone.

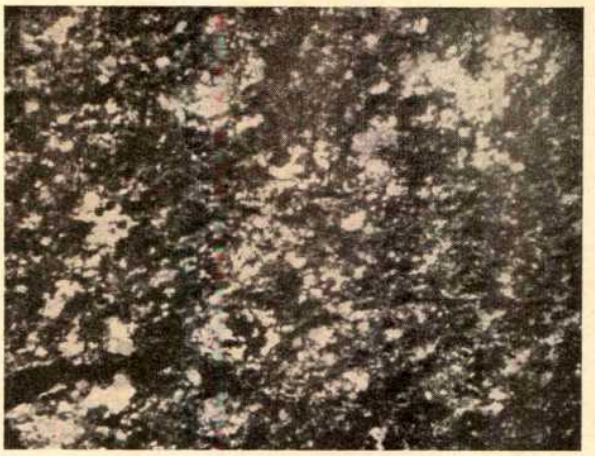

Fig. 6. Ground mass of 'type 1' inclusion in Renazzo. Note magnetite microchondrules and groups of partially fused magnetite microchondrules, which, from my previous experience, are quite exclusively characteristic for 'type 1 carbonaceous chondrites. Ordinary light. (×304)

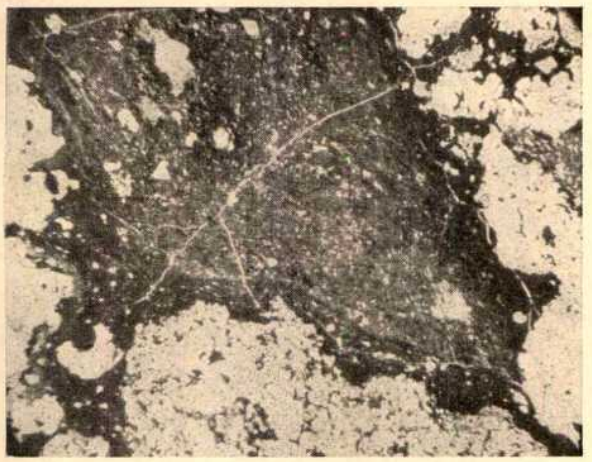

Fig. 4. Inclusion of a 'type 1' stone from a thin section of Renazzo, from the Smithsonian Museum, Washington. Note indications of extensive thermal metamorphism of inclusion; compared with Sharps meteorite (Fig. 2), there some flow structure is evident, and the mass seems to be partially squeezed in between the gaps of chondrules. Carbon enriched zones are present, similarly to those of Sharps meteorite, parallel to the margins and also surrounding a group of included chondrules from the host, along the upper left centre of the microphotograph. Ordinary light. (× c. 26)

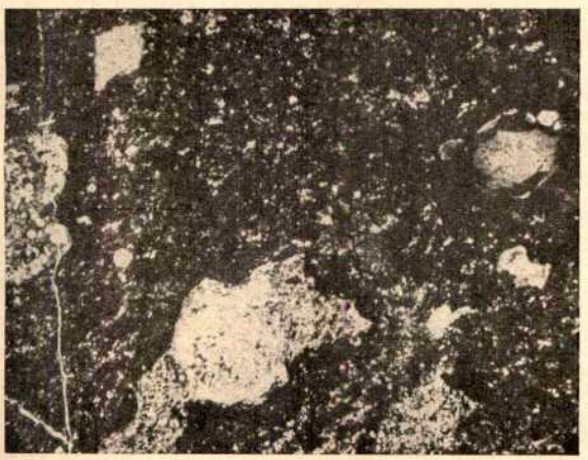

Fig. 5. Detail of the inclusion in Renazzo meteorite shown in Fig. 4. Note almost continuous opaque (carbonaceous) bands surrounding the two inclusions of the host along left half of the microphotograph, and also large glass microchondrule along right and several small glass microchondri along left centre. Ordinary light. (×96)

(6) *Mokoia*

With the exception of an obvious impact contaminant resin[9], no inclusions were observed in this meteorite, although Briggs and Kitto[10] reported a range of 0·5–2·1 per cent carbon in the distinct portions of the samples analysed. The total volatiles of eight different grains from the specimen in the Paris Museum were determined, and a range of between 2·58 per cent and 13·52 per cent was obtained—giving an average of 4·36 per cent. (The standard procedure for determining total volatiles of the stones consisted of heating finely ground powder which had been dried in a vacuum desiccator for 10 min to 1,000° C in a nitrogen atmosphere.) Compared with this, five determinations of total volatiles carried out on the Murray meteorite material only gave a range of 12·4–17·2 per cent. It would seem from the results of a minimum of three total volatile determinations that Mokoia may be the most inhomogeneous stone of all those so far investigated, with properties grading from 'type III' to 'type II' within different portions of the stone, even when material is taken from well beneath any known surface crust.

(7) *Kainsaz*

The co-existence of chondri and fragmented chondri with partially interlocking aggregates of well-formed olivine and other silicate crystals was noted in the 'type III' Kainsaz and, to a smaller extent, in the 'type II' Cold Bokkeveldt. The latter structures are generally similar to those in the chondritic-type achondrites, although major inclusions of achondritic matter have not so far been observed.

Future Potentialities of the Study of Associations between Diverse Types of Meteorites

It appears from the literature that research has, on the whole, been restricted to the more obvious cases of markedly brecciated stones. It is possible that much useful information could be obtained through a systematic search for, and study of, the less-evident associations and inhomogeneities, within both the carbonaceous and non-carbonaceous meteorites.

An unexpected example in support of this view became available to me during a recent field study at the village of Barwell, Leicestershire, with members of the University and Museum of Leicester and the British Museum. We were carrying out an investigation of the impact area of the shower of olivine–bronzite chondrites which fell there during December 24, 1965. I had an opportunity there of making a preliminary inspection of about 50 lb. of the material. It was observed that individual stones varied in shade from very light to medium dark grey; only further investigations could reveal whether these differences are caused by any variation of the percentage of carbon (which is expected to be within the 0·0*X* range for the type of stone in question) or by some other chemical or physical (porosity, etc.) factors. One specimen contained a globular olivine aggregate, 0·5–0·75 in. in diameter, which is unusually large for a chondrule-type structure: certainly it deserves further detailed study.

Such studies could well include an investigation of any chemical interaction between inclusion and host and a search for possible zoning, as well as the chemical and petrographical characterization of 'variable' stones (such as Mokoia and Barwell) which show apparently smooth transitions in properties without any sign of brecciation. In any investigation of these and other problems, the application of some of the more recently developed experimental techniques should prove particularly useful for the detection of changes in the carbonaceous complex—particularly so spot tests for the distribution of major and minor trace elements, infra-red and ultra-violet spectroscopy, gas chromatography and mass spectrometry.

Some Theoretical Considerations

The associations described here clearly point to a common parent body for at least some of the following types of meteorites; (1) Type I–type III carbonaceous chondrites–chondrites (Orgueil, Sharps). (2) Type I–type III carbonaceous chondrite (Renazzo). (3) Type II–type III carbonaceous chondrite (Mighei, Modoia). (4) Type II carbonaceous chondrite–ureilite (Cold Bokkeveldt). (5) Type II carbonaceous chondrite–achondrite (Cold Bokkeveldt). (6) Type III carbonaceous chondrite–achondrite (Kainsaz).

This covers the main range of carbonaceous and non-carbonaceous stony meteorites, with the exception of certain rarer varieties. In view, however, of the very considerable chemical and petrographical uniformity within the 'carbonaceous chondrite–chondrite series', it is likely that, even in cases where associations have not so far been observed in our studies of inclusions, the stones in question originate from identical or very similar parent bodies.

Before any profitable analysis of the possible mechanisms of the emplacements of the fragments can be undertaken, some genetical implications must be considered of the interrelations between volatile and non-volatile constituents of the 'carbonaceous chondrite–chondrite series' (ref. 4). It seems to me that the most likely interpretation of these is that, at the highest temperature stage of its cosmological history, the parent body had an incandescent cloud mantle, covered by cooler clouds of cosmic dust. The 'type I' stones are probably derived from the close-to-surface zones, where mild volcanic activity—pulsation through de-gassing—may have caused a limited amount of intermixing of the cool cosmic dust with spray particles from the marginal zones of the incandescent cloud and volatile condensates. This would explain the small spray diameters and high percentage of glass that was rapidly quenched.

Stones containing less volatile material would be derived from increasingly deeper zones of the parent body, and would have had less access to cosmic dust. They would have received greater quantities of spray particles from the more crowded and hotter portions of the incandescent cloud mantle and, furthermore, would have been subjected to a greater degree of heating subsequent to the final cohesion of the material of the stones from the incandescent clouds. Ureilites, and other types of achondrites, may represent localized spray condensates—that is, 'lavas'—which formed from the highly degassed or impact-shocked portions of the incandescent clouds. Alternatively, the features could be explained as being due to a more localized close-to-surface 'ash eruption'-type activity—the stones rich in volatiles coming from the regions farthest from the erupting vent. It is a possibility that the original vertical zoning, through the 'incandescent cloud mantle' model effect, was afterwards modified somewhat by localized volcanic eruptions and intrusions.

The previously observed shift of the volatilization curves towards lower temperatures with the increase of total volatiles content of the stones seems to favour the 'incandescent cloud' model (as discussed in ref. 11). Certain features of the inclusions, however, indicate occasional localized volcanic activity. Thus, the presence of higher volatile, thermally metamorphosed fragments in Sharps and Renazzo can be considered to have arisen from an upsurging column of dense incandescent cloud with perhaps partially solidified spray particles which may have engulfed low-temperature fragments near the surface. The exceptionally large gas bubble in the chondrule of 'Inclusion *C*' of Orgueil seems to indicate a sudden release of pressure; it is probable that this was due to the rapid ascent of the fragment in the course of eruptive activity.

The fact that all the inclusions observed so far have well-defined straight boundaries (with the possible exception of inclusion *B* of Orgeuil) excludes, of course, any possibility of water transportation and is an additional evidence for the essentially 'volcanic breccia'-type origin of the structures. However, in the terrestrial pyroclastics, some rounding of the individual fragments is not uncommon, particularly where more extensive and explosive volcanic activity has occurred. The absence of any sign of rounding, even in such soft material as that included in Sharps, indicates that the volcanic activity was of a mild character and of short duration, as would be expected for a parent body of relatively small dimensions.

Finally, the apparent absence of association between the carbonaceous chondrite and ureilite groups of high carbon stones, on one hand, and the enstatite chondrites, on the other, should be considered. The oxidized iron : reduced iron ratio of carbonaceous chondrites and possibly that of ureilites is the highest in all meteoritic matter. This would suggest that within the close-to-surface zones of the parent body, from which these stones are believed to originate, there was a somewhat hydrogen-depleted, oxidizing assemblage of gases escaping and forming a temporary atmosphere. The high carbon percentage, associated with an extremely low oxidized iron : reduced iron ratio of the enstatite chondrites, may indicate that these stones are derived from the close-to-surface zones of relatively larger parent bodies, in which the de-gassing products, throughout the entire period of de-gassing, remained more reducing as a result of the retention of a higher proportion of hydrogen, methane, and other reducing gases, due to a more intensive gravitational field. If the foregoing considerations are correct, then we should not expect any signs of association between the carbonaceous chondrite–ureilite group of 'oxidized' high volatile stones, and the enstatite chondrite group of 'reduced' ones. It is very likely, however, that a more detailed search would

reveal interbrecciation between enstatite chondrites of different types.

Finally, the anomalously high carbon : sulphur ratio of 2·36 of the inclusion of Sharps is significant in view of the mean of 0·59 for Type I carbonaceous chondrites. This may be explained as due to preferential escape in the course of the thermal metamorphism of the fragment of sulphur as sulphur vapour and sulphur dioxide, and the retention of amorphous carbon and graphite under the somewhat oxidizing conditions that prevailed. The even higher carbon : sulphur ratio for the ureilites of about 6·0 can be explained by the same mechanism, if more intensive heating is postulated: in this connexion analytical data regarding the ureilite-type fragments in Cold Bokkeveldt would be of considerable interest. On the other hand, de-volatilization under more reducing conditions would cause essentially the reverse trend, as then the bulk of sulphur is present as non-volatile ferrous sulphide and the carbon forms mainly volatile hydrocarbons. It is possible that the latter explanation would account for the low sulphur : carbon ratio of 0·06 for the enstatite chondrites and the even lower value (of the order of 0·01) for the ordinary chondrites.

These observations and considerations would seem to indicate that the very broad range of sulphur : carbon ratios of meteorites can be derived through de-volatilization of primordial matter (cosmic dust) of approximately uniform composition under differing temperatures and reducing or oxidizing conditions. Detailed investigations of the composition of inclusions of carbon, sulphur and other volatile elements or inclusions may give us further significant information in assessing the relative importance of the parameters, including the time involved.

I would like to thank Prof. J. D. Bernal, Birkbeck College, London (where much of the work was actually carried out), for encouragement, and Prof. J. Orcel (Paris), Prof. K. Strokay (Budapest), Dr. Henderson and Dr. B. Mason (Smithsonian Institution, Washington), Dr. H. Scholler (Museum of Vienna), Dr. H. B. Wiik (Helsinki), and Dr. G. F. Claringbull (British Museum (Natural History)) for specimens and the opportunity to study thin sections. I also thank Dr. K. Fredriksson (Smithsonian Institution, Washington) for information about his discovery of the inclusion in the thin sections in Sharps meteorite and for placing these at my disposal.

[11] Mueller, G., Shaw, R. A., and Takeshi, Ogava, *Nature*, **206**, 23 (1965).

I CONSIDER the studies contained in Prof. Mueller's article to be of great importance. Much has been shown by examining the single meteorite stone, but this work, for the most part, has consisted of investigations on the stone as a whole attributed to various classes. What Prof. Mueller has done in this way is to examine meteorites containing other types of meteorite as inclusions, thus demonstrating that they must have been derived from the same parent body.

I would like to direct particular attention to the study, by Dr. Fredriksson, of the Sharps meteorite and its bearing on the origin of carbonaceous meteorites 'type I'. At present, only preliminary observations have been made: in my opinion their bearing is conclusive; the Sharps meteorite contains at least one large inclusion of a 'type I' carbonaceous stone.

Two features of this observation call for particular attention. First, the inclusion is an angular fragment with generally defined straight boundaries against the surrounding chondrite. This indicates that it is a fragment broken from a larger, already formed, carbonaceous meteorite which has been incorporated, subsequent to its breaking up, in the then unconsolidated chondrite stone. Secondly, the fragment, as it is found, shows evidence of contact metamorphism, presumably in bands following the outline of the fragment as well as those of the included chondrules. This shows that at the time of inclusion the chondrules were hotter than the carbonaceous material although not so hot as to cause excessive degassing or boiling away of the volatile constituents.

It is clear that further investigation would throw much light on the origin of both types of meteorite. Prof. Mueller has put forward plausible accounts of these with which I am inclined to agree, but more may come out of a more detailed study. This should include a micro-chemical analysis point by point both inside and outside the inclusion to check how far the material had been altered and how far the contact metamorphism has affected the parent body. For this, electron probe investigations might be very useful and also electron spin resonance and nuclear magnetic resonance.

Some such studies will undoubtedly be carried out and it would be appropriate for much of it to be done in Britain, for the British Museum (Natural History) holds the most extensive collection of meteorites in the world. The personnel and apparatus do not yet exist in Britain for such studies to be carried out on an adequate scale. Unless such resources and manpower can be made available, a field of great promise in the age of spacial exploration of our planetary system could well be lost.

ESTIMATION OF ZINC-65 BACKGROUND LEVELS FOR MARINE COASTAL WATERS

By G. V. ALEXANDER and R. H. ROWLAND

Laboratory of Nuclear Medicine and Radiation Biology of the Department of Biophysics and Nuclear Medicine, School of Medicine, University of California at Los Angeles

WITH the increased possibility of a nuclear accident near or in the marine coastal environment a more accurate estimate of background radioactivity levels for elements such as zinc-65 is needed. Estimates of zinc-65 on the Pacific coast are complicated by the uncertainty of the contribution resulting from the Columbia River outflow. The average rate of input from this source is 30 c. zinc-65 and 700 c. chromium-51 per day[1]. Even at these relatively high levels dilution with sea water soon reduces the concentration to such a degree that direct measurement in sea water is impossible. Chemical concentration of zinc-65 in sea-water samples has generally

met with failure[2]. It has been demonstrated, however, that several marine species concentrate zinc so well that the determination of zinc-65 in tissues of these animals is relatively simple.

This article presents data on zinc and zinc-65 for marine tissues collected near to and remote from the Columbia River and correlates these data into a more accurate estimate of that level of contamination by zinc-65 which should be considered background.

During August of 1964 samples of *Mitella polymerus* (the goose barnacle), *Pisaster ochraceus* (the common coastal starfish) and *Mytilus californianus* (the California mussel) were collected from locations at and near the mouth of the Columbia River. These species were chosen for study since they can be obtained in large quantity at practically any location on the Pacific coast. A sample of *Crassostrea gigas* (oyster) was included for comparison with previous investigations of the Willapa Bay region. All tissues were dried by lyophilization before analysis. The normal sample size was 40–70 g of dry tissue. The radioisotope concentration of each sample was determined with the total-body counter at this University. (We thank Dr. N. S. MacDonald and his staff for the counting of all samples included in this report.) The stable element concentrations were determined with conventional optical emission and X-ray fluorescence techniques.

Table 1 outlines the data for zinc and includes, where reasonable counting accuracy could be maintained, data for chromium. Chromium-51 is the major γ-emitting isotope present in the river water as it passes Vancouver[1]. This element is added to the reactor cooling water as part of the purification process[3].

The present zinc-65 levels in *M. californianus* are generally in good agreement with values from previous studies[4,5], as is the value for the Willapa Bay oysters. It can be noticed that although the activity levels of the tissues of a species may vary by as much as sevenfold the specific activity is constant to within a factor of 1·4 and, as expected, serves as a relatively satisfactory index of the contamination level.

The specific activity of chromium decreases rather markedly in the order mussel, starfish and barnacle. This may indicate a food chain of mussel—starfish . . . barnacle with an equivalent hold-up time between starfish and mussel of between 40 days and 50 days as estimated from the radiation decay of chromium-51. The much lower, 2–3 times, zinc-65 and chromium-51 specific activity value for barnacle suggests that this animal receives much of its food from an area of lower contamination than its place of residence. Quite possibly this includes organic debris washed in from some distance seaward. In any event, it suggests that specific activity data must be applied cautiously in an area of rapidly changing levels such as are found in the Columbia River region.

An estimation of the contribution of these relatively high zinc-65 levels to the much lower values (17–200 pc./kg wet tissue) observed by Folsom[2] in the San Diego region (*c.* 1,200 miles) can be approached from several points of view. First, data reported by Watson[4] suggest that the zinc-65 concentration decreases in proportion to the 1·23 power of the distance from the river mouth. Extrapolation of these data to 1,200 miles indicates a concentration in *M. californianus* of 300–800 pc. zinc-65/kg wet tissue (1,900–5,000 pc./kg dry). A second estimate results from extrapolating the salinity data of Steffánson and Richards[6]. The decline in freshwater concentration indicated by these data agrees well with the decline in zinc-65 concentration observed for *M. californianus* along the Oregon coast. An extrapolation of these data indicates a zero contribution from the Columbia River at distances greater than 700 miles.

The general agreement between the extrapolation of Watson's data and the observations in the San Diego region seem to suggest that the Columbia River is the prime contributor to zinc-65 on the Pacific coast. However, determination of zinc and zinc-65 in the Atlantic oyster, *Crassostrea virginica*, carried out by Skauen and Rankin[7] during 1960 to 1963, indicates that the background level in the oyster is 30–50 pc. zinc-65/kg fresh tissue. The general agreement of this level with the San Diego data would suggest that this level of contamination is most likely due to fall-out or possibly nuclear submarine activity.

In order to resolve this last-mentioned point, several 'background level' samples were collected from the East coast, the Southern California coast and the Salton Sea. The Salton Sea sample should represent fall-out activity only. These data are presented in Table 2. The activity-levels again vary considerably while the specific activity-levels of zinc-65 are relatively constant. The higher specific activity for the Long Island Sound sample may indicate an effect due to nuclear submarine activity, but more likely indicates a greater contribution owing to fall-out washed from the surroundings as is possibly the case for the Salton Sea sample.

It is interesting to compare the zinc concentrating ability of the two types of barnacles by comparing their zinc

Table 2. 1964–65 BACKGROUND VALUES

Location	Animal	Concentration in dry tissues				
		Type of tissue	Zn p p.m.	^{65}Zn pc /kg	^{65}Zn/Zn pc /mg	Dry/fresh wt %
La Jolla, California	*Mitella polymerus*	Stems	150	92	0 61	30 2
		Bodies	910	684	0·75	18 4
	Mytilus californianus	Soft	91	35	0·39	23 1
Malibu, California	*Pisaster ochraceus*	HC	160	22	0 14	
Chesapeake Bay	*Crassostrea virginica*	Soft	10,200	456	0 05	7 60
Long Island Sound	*Venus mercenaria* "little neck"	Soft	214	276	1 29	20 4
Salton Sea	*Balanus amphitrite saltonensis*	Soft	193	516	2·68	18 6

concentration with that determined for their marine environment—0·86 μg zinc/l. for the Salton Sea and 6·4 μg zinc/l. at La Jolla. The body portion of *M. polymerus* was compared with the morphologically similar soft tissue dissected from *B. amphitrite saltonensis*. The concentrating factors were 26,000 and 44,000, respectively. These values are about an eighth of the value for *C. virginica* under similar conditions[8] but are essentially the same as the concentrating ability of *C. gigas*.

These data indicate that the present level of zinc-65 from fall-out has established a specific activity for this isotope which is relatively constant in the coastal environment at 0·05–2·7 pc. zinc-65/mg zinc. In order to compare this constancy with data from previous investigations the average zinc concentration for several foods was determined and applied to the 1958 and 1959 data of Perkins[9] and Murthy[10]. These data are shown in Table 3. Here again the relative constancy of the specific activity values is striking. Since approximately six years separate the data of these two tables, it is most likely that the data in Table 2 represent the fall-out from 1961 and 1962 tests while the data of Table 3 result from pre-1959 tests.

Table 3. 1958–59 BACKGROUND VALUES

Food	Reference	Concentration in fresh tissue: ^{65}Zn pc./kg	Zn p.p.m.	^{65}Zn/Zn pc./mg	Collection date
Clams	Murthy (ref. 10)	40	44	0·92	May '58

Eggs	Murthy (ref. 10)	6	13·5	0·44	Aug. '58
Milk	Murthy (ref. 10)	4	5·1	1 29	'59
Tomatoes	Perkins (ref. 9)	7·2	3·4	0·21	'59

Folsom[2] has demonstrated that manganese-54 is concentrated by as much as 6,000-fold in phytoplankton and by 2,000-fold in *M. polymerus* stems. Manganese-54 as fall-out debris was produced principally by the U.S.S.R. 1961 test series and no appreciable new input of manganese-54 has occurred since 1961 (ref. 11). During this investigation several samples contained sufficient manganese-54 to permit accurate determination. These results are presented in Table 4. As with zinc-65, the specific activity values of manganese-54 are more constant than the corresponding radioactivity levels.

Table 4. MANGANESE AND MANGANESE-54 IN DRY TISSUE

Location	Animal	Type of tissue	Mn p.p.m.	^{54}Mn pc./kg	^{54}Mn/Mn pc./mg
Ecola Beach, Oregon	*Mitella polymerus*	Stems	114	1,700	14·9
North Head, Illwaco, Washington	*Mitella polymerus*	Stems	154	2,230	14·5
Willapa Bay, Washington	*Crassostrea gigas*	Soft	59 1	1,060	18·0
La Jolla, California	*Mitella polymerus*	Stems	37 9	243	6·4

The concentrating ability of *M. polymerus* tissues for zinc and manganese may be used to estimate the late 1964 levels of zinc-65 and manganese-54 in Southern Californian sea water. For manganese-54 we may use *M. polymerus* stems to arrive at a sea-water value of 37×10^{-15} c. manganese-54/l. ($243 \times 0{\cdot}302/2{,}000$). For zinc-65 the body portion of the animal is more useful, yielding an estimate of $4{\cdot}5 \times 10^{-15}$ c. zinc-65/l. ($684 \times 0{\cdot}184/26{,}000$). If we use the specific activities shown in Tables 2 and 4 together with the average concentration of these two elements in sea water[12], two similar estimates are obtained, that is, 13×10^{-15} c. manganese-54/l. ($2 \times 10^{-3} \times 6{\cdot}4$) and $5{\cdot}8 \times 10^{-15}$ c. zinc-65/l. ($10 \times 10^{-3} \times 0{\cdot}58$). By a similar approach the zinc-65 concentration of the Salton Sea would be $2{\cdot}3 \times 10^{-15}$ c. zinc-65/l. ($0{\cdot}86 \times 10^{-3} \times 2{\cdot}68$).

The estimated values for manganese-54 in sea water are quite similar to those reported by Folsom when the sampling time difference is corrected for radioactive decay and for the seasonal changes in rate of fall-out as indicated by local air samples and the sea-water samples reported by Folsom. The apparent magnitude of this seasonal variation is sixfold with the minima occurring in mid-winter[13].

To estimate the concentration of radioelements such as zinc-65 in sea water by biological concentration alone, one must have accurate knowledge of the concentrating ability of the tissue or animal involved. However, if knowledge of the stable element concentration is available it is only necessary to select tissues known to concentrate the element of interest to arrive at an accurate value for the mean sea-water concentration. Present analytical techniques make it relatively easy to obtain accurate analysis for elements such as zinc, manganese and chromium in sea water and in biological tissues.

Should it not be possible to include a stable element determination a tissue of relatively constant concentration could be used. Of the tissues reported here, only two have been found to be of constant concentration, namely, the starfish hepatic caecum and the male gonad. The hepatic caecum contains 54 ± 20 μg zinc/g fresh tissue which is $0{\cdot}29 \pm 0{\cdot}11$ per cent zinc when converted to ash at 510° C. The male gonad contains $9{\cdot}0 \pm 1{\cdot}9$ μg zinc/g fresh tissue which is $0{\cdot}043 \pm 0{\cdot}008$ per cent when ashed. These values result from approximately fifty samplings conducted at several locations along the Pacific coast during the past few years.

To evaluate the background contamination level of zinc-65 on the Pacific coast, namely that resulting from the Columbia River plus that resulting from fall-out, it would seem essential to include analysis for manganese-54 to support that portion of zinc-65 assigned to fall-out and analysis for chromium-51 to evaluate the contribution from the Columbia River. (The relatively high and apparently constant level of chromium in the starfish male gonad together with the relatively low zinc value would suggest that this tissue would be particularly suited for the biological concentration of chromium-51 in the presence of zinc-65.) Even though the half-life of chromium-51 is only 27·8 days as opposed to 245 days for zinc-65 the effective concentration of chromium-51 would exceed that of zinc-65 for some 150 days and apparently is not removed as easily from the river plume as is zinc-65 (ref. 14). At present it seems reasonable to assume that there is no significant contribution to the Southern California coastal zinc-65 levels from the Columbia River and that essentially all the present level results from fall-out.

A similar approach, although not requiring the determination of chromium-51, would certainly improve the evaluation of excessive contamination in areas such as New London, Connecticut[7], where by external sampling it was apparently impossible to resolve the contribution from a nuclear submarine 'incident' from that which may have resulted from fall-out from the U.S.S.R. tests until the activity-level had subsided from a 250-fold increase to near background and approximately 18 months had elapsed.

This work was supported by a contract between the Atomic Energy Commission and the University of California.

EFFECTS OF X-IRRADIATION ON THE METABOLIC CHANGES ACCOMPANYING PHAGOCYTOSIS

By D R. J. SELVARAJ* and DR. A. J. SBARRA

Department of Pathology and Medical Research, St. Margaret's Hospital and Department of Obstetrics and Gynecology, Tufts University School of Medicine, Boston, Massachusetts

IT is well known that irradiated animals are generally more susceptible to infection than non-irradiated animals. A number of different host defence mechanisms against infection may fail to protect the irradiated animals—a major one being the ingestion and subsequent destruction of micro-organisms by the phagocytic cells. The effects of ionizing radiation on phagocytosis have been intensely investigated, but many reports are contradictory[1–3]. Some of these contradictions seem to depend on dosage, experimental animals and to a large extent on the assay procedures.

Particle uptake by polymorphonuclear neutrophils (PMN) is known to be accompanied by a number of metabolic changes in the phagocytes. For example, an increase in the rate of oxygen consumption and glycolysis and a large stimulation of the oxidation of glucose-1-^{14}C and formate-^{14}C have been reported to accompany phagocytosis by guinea-pig exudate PMN[4,5]. Furthermore, a variety of antimicrobial agents and hydrolytic enzymes are also known to be released from cytoplasmic granules of PMN during phagocytosis[6–7].

An investigation of the established phagocytic and metabolic alterations found in PMN following irradiation might not only shed light on possible mechanisms of host susceptibility but also might provide further insight into the phagocytic process. Thus, this initial study is directed towards establishing some baseline effects of irradiation on leucocytic metabolism in the absence and presence of particles. This article reports the results gained from this investigation. (A preliminary report has already been published[8].)

Guinea-pigs of both sexes weighing 300–400 g were used throughout these experiments. All common chemicals used were of reagent or analytical grade and obtained commercially. Radioactive substances were purchased from New England Nuclear Corporation, Boston, Massachusetts. Polystyrene spherules of 0·81μ diameter were obtained from the Difco Laboratories, Detroit, Michigan.

Peritoneal exudates were essentially prepared according to previously described procedures[4]. This in outline consisted of injecting intraperitoneally a 12 per cent sterile suspension of sodium caesinate into guinea-pigs. 12–18 h later the animals were killed, the peritoneal cavity was exposed and the exudate was aspirated. The peritoneal cavity was rinsed once with ice-cold Krebs–Ringer salt solution buffered with 2 mM phosphate buffer of *p*H 7·4 (wash solution). The exudate and washings (usually from three animals) were pooled and the PMN separated by centrifugation (110*g* for 4 min), washed twice with wash solution and brought up to desired volume. The amount of cellular material in the suspension was estimated by measuring the optical density of a suitably diluted suspension at 600 mμ. From the optical density either the number of cells present or the amount of cellular phosphorus was calculated from a pre-calibrated curve.

Oxygen consumption measurements were made by using conventional Warburg manometric techniques. 6-ml. microflasks with 1-ml. reaction mixture containing about $5{\cdot}7 \times 10^7$ PMN (100γ cellular phosphorus) were used. The reaction was terminated by immersing the flasks in crushed ice. After aliquots had been removed from the reaction mixture for microscopic examination the flasks were tightly stoppered and 0·1 ml. of a 30 per cent solution of trichloroacetic acid kept in the side-arm was tipped into the flask to precipitate protein and release bound carbon dioxide.

Phagocytosis, as monitored by light microscopy, was measured by an independent worker from coded slides. One hundred cells were counted from each sample.

For the assay of $^{14}CO_2$ the contents of the centre wells were transferred quantitatively to centrifuge tubes containing carrier potassium carbonate to yield a convenient weight of barium carbonate (16 mg). Barium carbonate was precipitated from the solution by the addition of 0·1 ml. of 2 M ammonium chloride followed by the addition of 0·5 ml. 20 per cent barium chloride. The barium carbonate precipitate was washed once with freshly distilled water and once with acetone. It was then resuspended in 0·5 ml. of acetone and transferred quantitatively to aluminium planchets with the aid of more acetone in order to gain an even spread. Self-absorption corrections were made from barium carbonate absorption curves prepared for use with the counter[9].

Lactate estimations were made from protein-free aliquots of the reaction mixture, at three different dilutions, by the method of Barker and Summerson[10]. Total and differential white blood cell counts were made by conventional techniques from blood obtained from the marginal ear vein.

Irradiation was carried out with a Picker X-ray therapy unit operated at 280 kVp. The cell suspensions were irradiated in thin-walled small glass test-tubes. At a target distance of 12 cm, the dose-rate was about 1,500 r./min with no added filtration. Whole-body irradiation was carried out in plastic cages at a target distance of 75 cm. The half-value layer was 3·4 mm of copper with an added Thoreus No. 3 filter and the dose-rate was 20 r./min. All doses were measured in air using a calibrated Victoreen dose-meter.

In vitro irradiation of exudate guinea-pig PMN with X-ray doses up to 50,000 r. had little or no measurable effect on the phagocytic and metabolic functions of these cells. Attempts to demonstrate an effect of X-rays by irradiating the cell suspension in 100 per cent oxygen atmosphere and/or preincubating the cells in order to deplete endogenous substrates were also not successful.

Preliminary experiments on whole-body X-irradiation of guinea-pigs established an $LD\ \frac{30}{60}$ of about 200 r. Total and differential counts were made on the peripheral white blood cells throughout the 30-day period. The animals developed leucopenia 2 days after being irradiated with 500 r. and 5–6 days after 100 r. which was persistent for 3–4 weeks. Deaths following irradiation usually occurred at, or soon after, the peak of leucopenia (about 500 white blood cells/mm^3). As the leucopenia progressed, the white blood cell differential shifted to a higher percentage of lymphocytes and monocytes.

* Charlton Fellow, Tufts University School of Medicine.

The effects of high dose (1,500 r.) whole-body X-irradiation on the phagocytic and the related abilities of the casein-induced exudate PMN to oxidize glucose-1-^{14}C and formate-^{14}C were studied. Two different experimental conditions were set up: In one, six animals were injected with casein and, 18 h later, all were irradiated. The cells were collected and examined 1 h after irradiation. In another, six different animals were exposed to X-irradiation and 6 h later casein was injected. The resulting exudates were collected 18 h later for investigation. Exudate PMN obtained from non-irradiated animals were included and acted as our controls. A sub-optimal ratio of particles to phagocytes (100 : 1) was used with the hope that any alterations in the phagocytic–metabolic activity might be more readily detected. The results of these experiments are presented in Table 1. It is seen that the PMN induced after the high dose of X-irradiation phagocytized poorly and also exhibited a lowered phagocytic–metabolic rate. The experiment was repeated using cells which had been pre-incubated for a 2-h period. The particles and the labelled substrates were then tipped in from the side-arm and all the parameters shown in Table 1 were re-examined for a further 30 min. The results obtained after this period of pre-incubation were similar to those reported in Table 1 (for this reason they are not shown), though the metabolic rate was reduced by about 20 per cent in all groups.

Experiments conducted with low dose of whole-body X-irradiation revealed that a decreased phagocytic ability and metabolic activities of the PMN could be demonstrated on the ninth and third post-irradiation day, with 50 r. and 100 r. respectively. Some decrease in metabolic activity was evident in the groups exposed to 100 r. as early as 2 days after irradiation (Table 2). The reaction was carried out for a longer period of time (60 min) in order to determine whether the phagocytic and metabolic activities of the PMN collected from irradiated animals declined faster.

It would seem that the changes observed in the metabolism and phagocytosis of exudate PMN obtained from irradiated animals are related to the time elapsed after exposure to irradiation in addition to the dose of irradiation. Thus the period of investigation was extended to 30 days with a group of thirty-six animals exposed to 100 r. Respiration, glycolysis and production of radioactive carbon dioxide from glucose-1-^{14}C, glucose-6-^{14}C, succinate-1-^{14}C and formate-^{14}C were measured in the absence, and presence, of particles. PMN obtained from non-irradiated animals were used as controls with each experiment. Some of the results are summarized in Fig. 1.

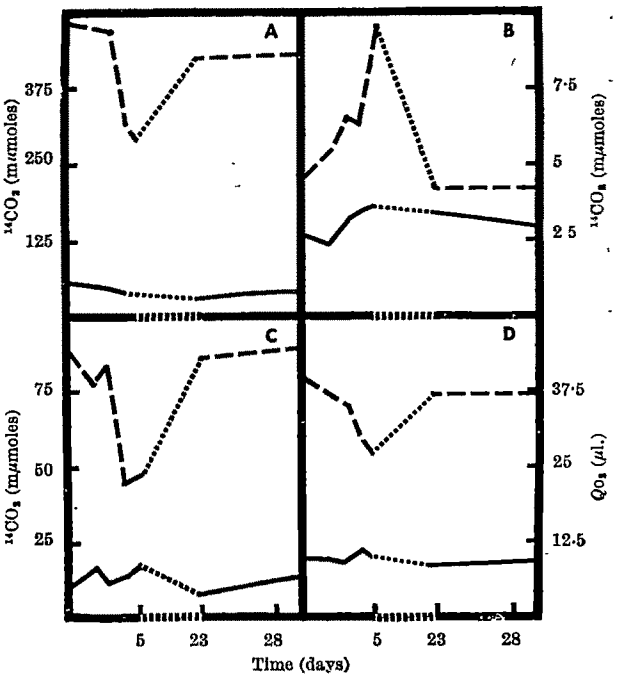

Fig. 1. Effects of whole-body irradiation on resting and phagocytizing PMN. See Table 1 for details. Control (non-irradiated) values are on X-axis: solid lines and broken lines represent resting and phagocytizing cells, respectively. *A*, $^{14}CO_2$ production from glucose-1-^{14}C; *B*, $^{14}CO_2$ production from glucose-6-^{14}C; *C*, $^{14}CO_2$ production from formate-^{14}C; *D*, oxygen consumption

Random deaths of six of the irradiated animals (out of thirty-six) occurred between the fifteenth and twenty-fifth day after irradiation. Between the fifth and fourteenth day after irradiation, the guinea-pigs did not respond to the challenge with casein. Very thin exudates, containing mostly the injected casein, was found in the peritoneal cavity. However, despite the severe leucopenia with a high percentage of mononuclear white blood cells that is seen as a result of X-irradiation, the exudate

Table 1. EFFECTS OF HIGH DOSE WHOLE-BODY X-IRRADIATION (1,500 r.) ON THE METABOLISM OF PMN IN THE ABSENCE AND PRESENCE OF PARTICLES

Groups	Substrates	Q (μl.)		$^{14}CO_2$ (mμmoles)		Lactate (μmoles)		Particle entry
	Particles	−	+	−	+	−	+	
Non-irradiated:	Glucose-1-^{14}C	8·5	30·8 (362)	54·9	447 (814)	3·4	3·1	+ + +
	Formate-^{14}C	8·7	26·9 (309)	7·5	51·2 (683)	1·4	1·5	+ + +
Irradiated with induced PMN in peritoneal cavity (18 h before irradiation)	Glucose-1-^{14}C	8·4	30 6 (364)	62·2	476 (765)	3 5	3 3	+ + +
	Formate-^{14}C	9·2	28·9 (314)	8·6	57·1 (664)	1 4	1·7	+ + +
Irradiated and PMN induced (18 h after irradiation)	Glucose-1-^{14}C	11·2	29 9 (267)	71·9	355 (494)	2·9	2 5	+ +
	Formate-^{14}C	11·5	21 1 (183)	19·4	46·8 (241)	1·1	1·2	+ +

All values are for 30-min reaction period and standardized for 100 cellular phosphorus—average of duplicate reaction flasks Particles used were 0·81μ polystyrene at a particle to PMN ratio of 100. (Figures in parentheses refer to the percentage of stimulation observed due to phagocytosis.) + + +, + +, +, are used to denote the efficiency of phagocytosis—approximately 90, 60, and 30 per cent of the PMN having twenty or more particles per cell respectively.

All values are for 60 min reaction period. See Table 1 for additional details.

differential remained the same throughout the experimental period (that is, more than 95 per cent PMN).

It can be seen from Fig. 1 that the phagocytic capacity of the exudate PMN decreased between the third and twenty-second day after irradiation. Simultaneous inhibition of the phagocytic respiration and oxidation of glucose-1-^{14}C and of formate-^{14}C are observed. We also detected a significant decrease in lactate production (from 3·5 to 2·3 μmoles/100γ cellular phosphorus/30 min on the fifth day after irradiation) However, the oxidation of glucose-6-^{14}C was significantly stimulated following X-irradiation. Succinate oxidation was stimulated slightly during this period. Although the phagocytic ability appeared to be normal by the twenty-third day after irradiation, the metabolic properties of these PMN were not completely normal throughout the 30-day observation period.

The stimulation of the oxidation of glucose-6-^{14}C and the concurrent inhibition of the oxidation of glucose-1-^{14}C due to X-irradiation results in a significant change in the ratio of these two carbon atoms of glucose oxidized by PMN. This alteration occurs both with phagocytizing and resting cells, and causes a decrease of more than 65 per cent in the ratio on the fifth day after irradiation (Table 3).

Lethal effects of whole-body irradiation have been ascribed[11] to at least three major syndromes: (*a*) neurological at doses of more than 30,000 r.; (*b*) gastrointestinal at doses between 1,000–30,000 r.; (*c*) haemopoietic at doses of a few hundred r. The haemopoietic syndrome, which occurs at moderately low doses, is characterized by bone marrow aplasia leading to infection, haemorrhage and anaemia. The increased susceptibility to infection, which is the major cause of the ensuing death, suggests that the host–parasite interaction has altered.

A considerable amount of work has been undertaken on the effects of irradiation on phagocytosis. However, to the best of our knowledge, no reports have appeared which describe the effect of irradiation on the metabolic activities of the phagocytizing cell. Our findings in the present experiments are essentially in agreement with those of previous workers. For example, Wagner *et al.*[12] found a 20 per cent inhibition of respiration with doses of 20,000–100,000 r. with no measurable effect on the rate of glycolysis. Levy and Ketchel[13] have shown that amoeboid movements of leucocytes are not inhibited unless doses of 200,000 r. were given.

The possible effects of X-irradiation on the exudate PMN under *in vivo* conditions were investigated by exposing guinea-pigs containing a pre-induced exudate in the peritoneal cavity (casein injected 16 h prior to irradiation) to 1,500 r. The phagocytic and metabolic activities of these cells were similar to those obtained from non-irradiated animals. However, the same amount of irradiation decreases the phagocytic and metabolic properties of PMN-induced 6 h post-irradiation. These results would indicate that the influences of irradiation on the leucocyte metabolism are due to an indirect effect.

Simultaneous studies on the leucocyte levels in the peripheral blood indicate that an irradiation effect is evident prior to the development of a pronounced leucopenia. Thus a single dose of 100 r. decreases the phagocytic and associated metabolic functions of exudate PMN between the third and twenty-third days following irradiation. However, leucopenia is noticed on the sixth day after irradiation, with the peak occurring about the tenth day. It should also be noted that the effect is accentuated with time. Recovery to the normal phagocytic ability is evident on the twenty-third day. Harris[14] reported the occurrence of leucopenia between the fourth and twenty-second day in guinea-pigs exposed to 150–170 r. whole-body irradiation from a cobalt-60 source.

Table 3. GLUCOSE-1-^{14}C AND GLUCOSE-6-^{14}C OXIDASE ACTIVITIES OF IRRADIATED AND NON-IRRADIATED PMN DURING PHAGOCYTOSIS

Conditions	Particles	$^{14}CO_2$ (mμmoles) produced from Glucose-1-^{14}C	$^{14}CO_2$ (mμmoles) produced from Glucose-6-^{14}C	Ratio C_1/C_6	Particle uptake
Non-irradiated (controls)	−	55	2·4	23	
	+	490	5·8	85	+ + +
Irradiated-100 r. (5 days post-irradiation)	−	46	5·4	8·6	
	+	290	9·6	30	+

See Table 1 for details.

Many authors have reported the existence of a general correlation between the peripheral granulocyte count and susceptibility to infection (see review by Cronkite and Brecher[11]). However, Shechmeister and Fishman[15] have demonstrated a decreased migration of blood leucocytes of rats and rabbits which could not be ascribed to leucopenia or plasma factors. They suggested that the phagocytic and digestive functions of rat leucocytes following whole-body irradiation are altered[16]. Donaldson *et al.*[17] have demonstrated that mice and rabbit peritoneal macrophages show a suppression of intracellular digestion of chicken erythrocytes and yeast cells following whole-body irradiation both by *in vitro* and *in vivo* tests. Our metabolic studies with the use of radioactive substrates, aided by microscopic observations, tend to support the hypothesis of a functionally impaired phagocyte. These results are especially interesting in view of the fact that the differential count of the cells used for investigation remained constant throughout the experimental period (more than 95 per cent PMN). Thus together with impaired particle uptake, PMN isolated from irradiated guinea-pigs show decreased glycolytic and respiratory rates, and decreased rates of oxidation of glucose-1-^{14}C and formate-^{14}C. All these parameters are known to be stimulated during phagocytosis[4,5]. However, the significance of these stimulations is still obscure. It has been suggested that the increased lactate production during phagocytosis causes the granules of PMN to lyse and release a variety of hydrolytic enzymes and antibacterial agents due possibly to an intracellular decrease in *p*H (refs. 6 and 7). Thus the decreased lactic acid production following irradiation could be responsible for the decreased phagocytic activity and a subsequent loss in the killing ability of the PMN. Also, the formation of hydrogen peroxide by the increased oxidation of reduced triphosphopyridine nucleotide has been demonstrated and invoked to act as the antimicrobial agent[18]. The decreased formic oxidase activity by PMN of irradiated animals might again suggest an altered bactericidal activity. Experiments designed to examine these possibilities are at present being carried out.

It has been shown that PMN preferentially oxidize glucose-1-^{14}C to a significantly greater extent than glucose-6-^{14}C, resulting in a high C_1/C_6 ratio for glucose utilization[4]. It is interesting that this ratio decreased about 33 per cent following whole-body irradiation both in the resting and phagocytizing PMN. This was due to both decreased glucose-1-^{14}C oxidation and increased glucose-6-^{14}C oxidation (Table 3). Since the oxidation of glucose-6-^{14}C and glucose-1-^{14}C involves DPN and TPN as co-factors, respectively, it is interesting to speculate on the part that the altered oxidized-reduced DPN/TPN ratio could play in the phagocytic ability of these cells.

Finally, it should be noted that essentially all the metabolic parameters investigated are affected by doses of irradiation as low as 100 r., and that these parameters do not completely return to the normal state as late as 30 days after irradiation. However, the phagocytic ability of the cell appears normal as early as 21 days after irradiation. These results suggest that the PMN, despite altered metabolism, is able to 'phagocytize normally' only because the cell has now lost its selective membrane permeability and that it is now possible for it to take up particles indiscriminately. This hypothesis is amenable to experimentation and it is actively being pursued.

This investigation was supported by the U.S. Atomic Energy Commission and by a U.S. Public Health Service research grant from the National Cancer Institute. We thank George Daynes and Mrs. Doris Crocker for their

help in preparing this report and Miss Lolita Dy Serrana for technical assistance.

HIGH-PERFORMANCE HYDROCARBON FUEL CELLS WITH FLUORIDE ELECTROLYTES

By DR. E. J. CAIRNS
General Electric Research Laboratory, Schenectady, New York

IT has been reported that aqueous caesium carbonate and bicarbonate are satisfactory fuel-cell electrolytes for use with carbonaceous fuels such as ethylene[1] and methanol[2]. An attempt to extend the use of the carbonate and bicarbonate electrolytes to include saturated hydrocarbon fuels showed that the fuel cell performance was significantly lower with paraffins than with the olefines and partially oxygenated hydrocarbons such as methanol[3].

The effects on the fuel-cell performance of fuel gas flow rate, electrolyte flow rate, and operating temperature, and the shape of the current density-voltage curve for a platinum-black anode all indicated a diffusion-limited process for the fuel in the electrolyte phase[3] (for example, in the meniscus or electrolyte film in the pores of the electrode). This led to the conclusion that the product of solubility and diffusion coefficient for the fuel in the electrolyte was probably very low. With this conclusion in mind, an attempt was made to increase the solubility of the hydrocarbons in the caesium-salt electrolyte by replacing some of the carbonate anion by fluoride, since hydrofluoric acid is known to enhance the solubility of saturated hydrocarbons in aqueous solution[4] and since the fluoride anion is probably not adsorbed[5,6].

The apparatus used in the present work consisted of a 'Teflon' fuel cell[2] enclosed in a forced-convection air thermostat. The electrodes were porous, 'Teflon'-bonded platinum black supported on 45-mesh platinum gauze and had an active geometric area of 11·4 cm². The electrocatalyst content of the electrodes was 51 mg/cm², with a specific area of 20 m²/g. (The procedure for preparing the electrodes has already been described[9].) The starting electrolyte was an 87 weight per cent aqueous solution of caesium carbonate, prepared according to methods previously described[7,8]. Baker and Adamson reagent grade 48 per cent hydrofluoric acid was added (see later). The hydrocarbon fuel was Matheson instrument grade propane of 99·5 per cent minimum purity, and the oxygen was electrolytic grade, 99·6 per cent minimum purity.

The electrical characteristics of the anode, the cathode, and the cell as a whole were measured on a resistance-free basis with the aid of an interrupter[2,10]. The potentials of the anode and cathode were measured against a reversible hydrogen electrode in the same electrolyte and at the same temperature. Current density-voltage data were taken at steady state, usually 2–5 min after a change in current.

The fuel cell was operated at 150° C, where the best performance was observed using propane as the fuel and caesium carbonate as the electrolyte. The anode performance under these conditions was 6·7 m.amp/cm² at an anode versus hydrogen reference potential of 0·5 V (E_{ar} = 0·5 V). The electrolyte was then drained from the cell (total electrolyte volume in the circulation system was 200 cm³) and 25 cm³ of 48 per cent hydrofluoric acid was added. This converted a fraction of the original caesium carbonate to caesium fluoride. The electrolyte was then concentrated to a composition corresponding to a boiling point of 160° C, and returned to the fuel cell. After the current density-voltage data had been obtained using a given electrolyte mixture, an electrolyte sample was removed for analysis, and hydrofluoric acid added as before.

Some of the results obtained from this series of experiments are shown in Fig. 1. The numbers on the curves indicate the number of additions of hydrofluoric acid that had been made to the original caesium carbonate electrolyte. Noteworthy is the change in the shape of the current density-voltage curve from that of a diffusion-limited anode reaction (additions 1–6) to that of an electrochemical rate-determining process (Nos. 8–13), the latter rate being an exponential function of the anode overvoltage. These results indicate that the product of the solubility and diffusion coefficient for propane in the electrolytes resulting from more than six additions of hydrofluoric acid is significantly greater than in the initial caesium carbonate electrolyte.

The effect of electrolyte composition on the rate of the anodic oxidation of propane on platinum black at 150° C and at an anode versus hydrogen reference potential of 0·5 V is shown in Fig. 2. Fig. 2 was prepared from the results of the chemical analyses of the electrolyte samples and from the current density-voltage data including those in Fig. 1. Fig. 2 shows a striking increase of the rate of

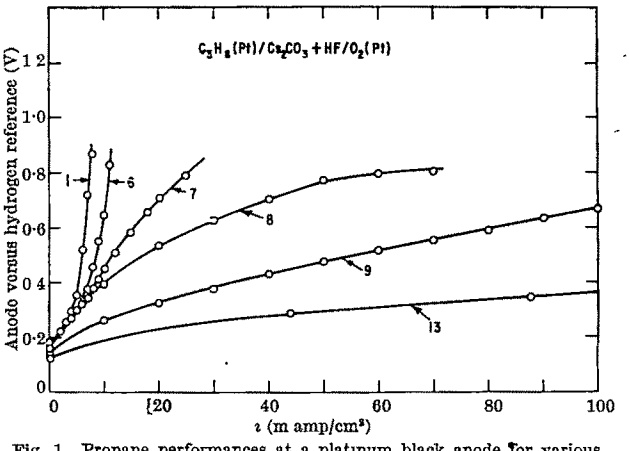

Fig. 1 Propane performances at a platinum black anode for various numbers of additions of hydrofluoric acid to the original caesium carbonate electrolyte The numbers on the curves indicate the number of additions of hydrofluoric acid made. Cell No. 8058-20. T = 150° C

anodic oxidation of propane with increasing F^-/Cs^+ ratio amounting to a factor of almost a hundred. Additions of hydrofluoric acid required to produce a value of F^-/Cs^+ in excess of 3·3 were not made because they would have reduced the atmospheric boiling-point of the electrolyte to a value of less than 160° C. The break in the curve corresponds closely to the *p*H 7 point rather than to the equivalence point (which is slightly alkaline), suggesting that an acidic electrolyte is necessary for improved performance.

The results in Figs. 1 and 2 indicate that at least two factors are responsible for the improvement in the current density at a given anode overvoltage: the solubility-diffusion coefficient product for propane in the electrolyte was increased to a point where dissolved fuel diffusion no longer limited anode performance; further increases in the acidity of the electrolyte beyond that necessary for improved mass transport rates resulted in further increases in the electrochemical rate constant.

The current density-voltage relationships for the anode versus reference, cathode versus reference and cathode versus anode are shown in Fig. 3 for the electrolyte composition that gave the best performance. A current density of 400 m.amp/cm² was obtained at nearly 0·2 V (resistance-free). The maximum power density for this cell (80 mW/cm²) is, to the best of my knowledge, higher than that for any previously reported direct hydrocarbon fuel cell operated under any conditions. This suggests that there may be some specific effect associated with the fluoride anion, resulting in an improvement in performance over that available using other strong aqueous acids.

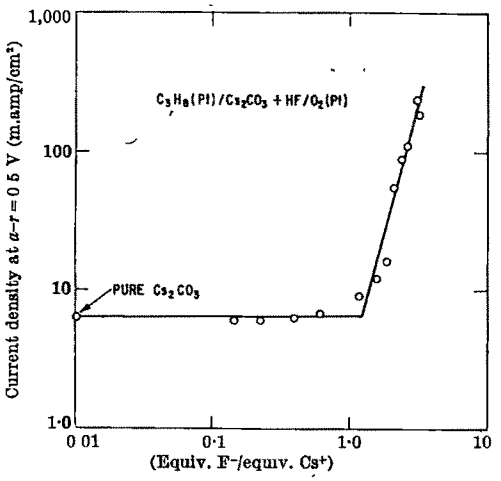

Fig 2. Effect of the ratio of fluoride to caesium (by equivalents) on the current density of a propane anode at a potential of 0·5 V versus reversible hydrogen. Cell No 8058-20. $T=150°$ C

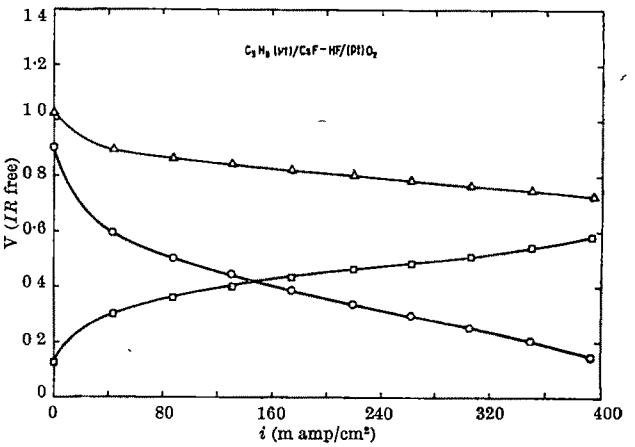

Fig 3. Current density voltage curves for a propane anode (□) and an oxygen cathode (△) versus reversible hydrogen, and the anode versus cathode (○), all on a resistance-free basis. Electrolyte: caesium fluoride, 29·3 mole per cent; hydrofluoric acid, 60·9 mole per cent; water, 9·8 mole per cent. Cell No. 8058-20. $T=150°$ C

It can be concluded that the ternary system caesium fluoride–hydrofluoric acid–water comprises a family of electrolytes suitable for high-performance saturated hydrocarbon fuel cells. Two effects differentiate this system from the caesium carbonate–water system: increased hydrocarbon solubility and diffusivity, and a greater overall rate for the electrochemical oxidation. Comparison of the present results with those for propane using other strong acid electrolytes leads to the suggestion of specific differences related to anion effects.

I thank Mr. G. J. Holm for his help in performing the experiments, and Mr. L. D. Sangermano and Dr. E. L. Simons for their analyses of the electrolyte solutions. This work is a part of a programme under contracts with the U.S. Army Engineer Research and Development Laboratories, Fort Belvoir, Virginia, to develop a technology which will facilitate the design and fabrication of practical military fuel cell power plants for operation on ambient air and hydrocarbon fuels.

AGGREGATION OF GUINEA-PIG PLATELETS BY ADENOSINE DIPHOSPHATE

By DR. JAY W. CONSTANTINE
Department of Pharmacology, Medical Research Laboratories, Chas. Pfizer and Co., Inc., Groton, Connecticut

THE aggregation of human, pig, and rabbit platelets caused by adenosine diphosphate (ADP), and its inhibition by adenosine are now well documented (refs. 1–8). Cuthbertson and Mills[3] showed that rat platelets aggregate in response to ADP, and that adenosine fails to inhibit ADP in this species; this has recently been confirmed[9].

By use of the turbidimetric method of Born[10] it is possible to record continuously changes in optical density of platelet-rich plasma caused by platelet aggregation, and by its spontaneous reversal. The optical density of citrated platelet-rich plasma of the aforementioned species decreases almost immediately on addition of suitable concentrations of ADP. This decrease is progressive for 3–4 min, after which the optical density remains constant for 20–30 sec, and then starts to increase toward the initial level, which is attained in 6–8 min; this 'recovery' is due to disbanding of the platelet aggregates[10], caused, it is assumed[10,11], by the degradation of ADP with the consequent formation of breakdown products which inhibit ADP.

This article describes results of the investigation of ADP-induced aggregation of guinea-pig platelets. Platelet-rich plasma was obtained from male Hartley strain guinea-pigs as previously described for the rat[9]. Platelet aggregation was investigated by the method of Born[10].

Experiments were performed at 23° C; concentrations of drugs refer to those in citrated platelet-rich plasma. Experiments were performed at least four times, each with a different pool of platelet-rich plasma (14–20 guinea-pigs for each pool).

Platelet aggregation was proportional to the concentration of ADP, as shown in Fig. 1. The extent of platelet aggregation caused by a given concentration of ADP varied somewhat in different pools of platelet-rich plasma. Guinea-pig platelets responded to concentrations of ADP lower than those found necessary by Born and Cross[2] to aggregate human and pig platelets in citrated plasma. Near-threshold concentrations of ADP resulted in a typical aggregation curve—a decrease in optical density followed by a return to, or near, the initial level (Fig. 1*A*). Slightly higher concentrations of ADP resulted in a biphasic aggregation curve; the decrease in optical density caused by ADP was followed by the usual increase toward the initial level, but this was interrupted by a plateau, and, after that, by a second phase of decreasing optical density (Fig. 1*B*). With still higher concentrations of ADP, the curve was one of progressive decline in optical density (Fig. 1*C*). Even with the higher concentrations of ADP, the optical density returned to, or near, the initial level, but not until approximately 30 min after the addition of ADP. ADP-induced aggregation of guinea-pig platelets was not inhibited by adenosine (Fig. 2). Epinephrine and 5-hydroxytryptamine (5-HT), both at 10^{-5} M, did not cause aggregation of guinea-pig platelets.

The results show that guinea-pig platelets are more responsive to the aggregating action of ADP than are the platelets of man and pig[2], and that adenosine does not inhibit ADP-induced aggregation of guinea-pig platelets. Born and Cross[12] reported that cat platelets in citrated plasma respond to lower concentrations of ADP than do human and pig platelets, and that ADP-induced aggregation of cat platelets is not inhibited by adenosine. Examination of the aggregation curves of Born and Cross with cat platelets (Fig 1 of ref. 12) shows that at concentrations of ADP slightly above threshold, a biphasic response was obtained, similar to that described here with guinea-pig platelets. Comparison of their figure with Fig. 1 of this article shows that cat and guinea-pig platelets are approximately equal in their responsiveness to ADP. The greater responsiveness to ADP of cat and guinea-pig platelets could be the result of a greater inherent sensitivity to ADP of these platelets. Another possibility is suggested by the notion that the spontaneous dispersal of ADP-induced platelet aggregates is the result of ADP degradation, and the concomitant formation of ADP inhibitors (namely, adenosine and adenosine monophosphate)[10,11]. Since exogenous adenosine does not inhibit ADP in cat or guinea-pig plasma it might be argued that the greater responsiveness to ADP of cat and guinea-pig platelets is due to the ineffectiveness of adenosine as an inhibitor of ADP (this argument would be based on the assumption that adenosine is a product of ADP degradation in cat and guinea-pig plasma). But adenosine also fails to inhibit ADP-induced aggregation of rat platelets[3,5], yet the aggregation curves obtained with rat platelets resemble those obtained with human[3] and rabbit platelets[3,5], but not those obtained with cat[12] and guinea-pig platelets. Cuthbertson and Mills[3], working with heparinized rat plasma and citrated rabbit plasma, found that rat platelets were more responsive to ADP than were rabbit platelets. Spaet and Zucker[13] have shown that human platelets are more responsive to ADP in heparinized plasma than they are in citrated plasma. It is possible, therefore, that the findings of Cuthbertson and Mills are due to the effects of the anticoagulants they used. It thus appears that differences in responsiveness to ADP and in the shape of aggregation curves obtained with cat and guinea-pig platelets, on one hand, and with human, pig, and rat platelets, on the other, are not determined solely by whether or not adenosine inhibits ADP.

As mentioned earlier, spontaneous dispersal of ADP-induced platelet aggregates may be due, in part, to degradation of ADP. An apparent increased sensitivity of platelets to ADP might, therefore, be a manifestation of increased stability of ADP in the plasma. To investigate this possibility in the guinea-pig, ADP, 3×10^{-7} M, was incubated in guinea-pig platelet-rich plasma for various time intervals before the commencement of stirring. The results are shown in Fig. 3. When stirring was started immediately after the addition of ADP, a typical response was obtained (Fig. 3*A*). When ADP remained in contact with platelet-rich plasma for 3 min before stirring, there was a loss in activity (Fig. 3*B*), and between 6 and 9 min activity was not evident (Figs. 3*C* and 3*D*). There is thus an apparent paradox in that, on one hand, within 9 min after the addition of ADP to platelet-rich plasma in the absence of stirring, the nucleotide was inactivated

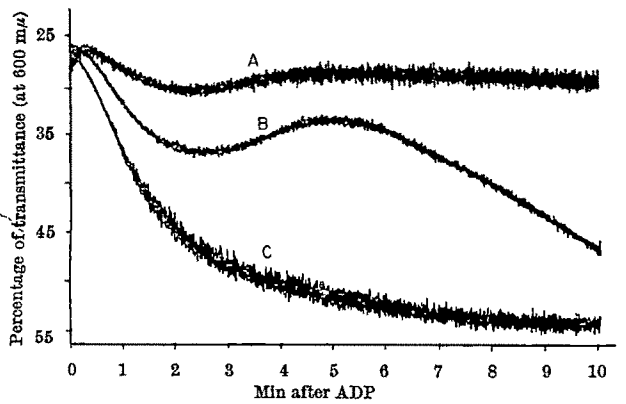

Fig. 1 Changes in optical density of platelet-rich guinea-pig plasma caused by ADP added at zero time in concentrations of: (*A*), 2×10^{-7} M; (*B*), 3×10^{-7} M; (*C*), 5×10^{-6} M. In this and in succeeding figures the ordinate was calibrated in transmittance units with the colorimeter

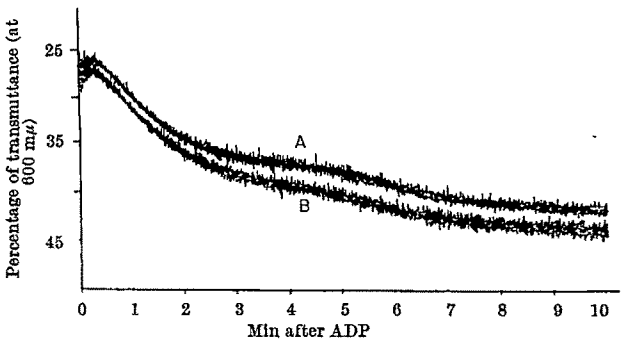

Fig. 2. Changes in optical density of platelet-rich guinea-pig plasma caused by ADP alone, and with adenosine. ADP (3×10^{-7} M) added at zero time to plasma which had been incubated 10 min at 23° C with: (*A*), 0·154 M sodium chloride, (*B*), 1×10^{-5} M adenosine

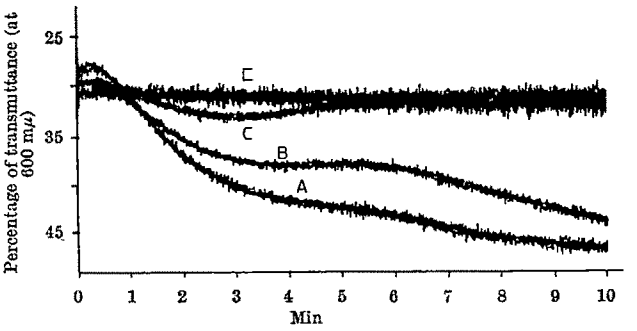

Fig. 3. Changes in optical density of platelet-rich guinea-pig plasma caused by ADP. Stirring was started at zero time in samples of plasma which had been incubated at 23° C with ADP 3×10^{-7} M for following times. (*A*), 0 min; (*B*), 3 min; (*C*), 6 min; (*D*), 9 min.

to the extent that there was no detectable platelet aggregation on subsequent stirring; on the other hand, when the same concentration of ADP was added with immediate stirring, platelets were still aggregating 10 min after the addition of ADP (Fig. 3*A*). One obvious explanation of this result is that ADP inactivation is curtailed when platelets aggregate, compared with its inactivation in the presence of non-aggregated platelets. The inactivation of ADP in platelet-rich plasma of the rabbit and rat has recently been investigated in the manner described here[9]. In both these species the time course of ADP inactivation is in accord with expectation based on the shape and time course of the aggregation curves, assuming, of course, that inactivation of ADP is contributory to disbanding of platelet aggregates. In these two species there is thus no evidence to indicate that the rate or extent of ADP inactivation differs according to whether or not platelets aggregate. The question as to whether or not such differential inactivation of ADP occurs in guinea-pig plasma cannot now be settled.

The biphasic nature of the aggregation curve, obtained with suitable concentrations of ADP in guinea-pig platelet-rich plasma, suggests another possible mechanism for the apparent greater stability of ADP in the presence of aggregated guinea-pig platelets. Near-threshold levels of ADP did not result in a biphasic curve (Figs. 1*A* and 3*C*), but concentrations slightly above threshold did (Figs. 1*B*, 2*A*, 3*A*), while still higher concentrations resulted in a progressively declining curve which was not interrupted by a plateau (Fig. 1*C*). Consideration must be given to the possibility that aggregation of guinea-pig platelets is associated with the release from such platelets of an aggregating substance. The results are now discussed hypothetically, on the basis of this possibility. Near-threshold levels of ADP result in the aggregation of only a small proportion of the platelets, and hence the release from them of a small amount of aggregating substance. The platelet aggregates disband, due, presumably, to the inactivation of ADP, and the optical density of the plasma returns to the initial level (Fig. 1*A*). With higher concentrations of ADP, more platelets aggregate as indicated by a greater decrease in optical density (Fig. 1*B*). The optical density remains constant for about 30 sec (from 2 to 2·5 min, Fig. 1*B*), indicating that aggregation and disbanding of aggregates are proceeding at equivalent rates. The optical density then starts to increase as disbanding of aggregates exceeds aggregation—'recovery' has started. However, aggregation has proceeded to the extent that sufficient aggregating substance has been released from the platelets to start a second phase of aggregation. Once again the optical density remains constant as the rate of aggregation equals that of disbanding (Fig. 1*B*, at 5 min); finally, aggregation exceeds disbanding, and the optical density decreases again. With still higher concentrations of ADP, sufficient numbers of platelets have aggregated to result in the release of aggregating substance early enough to prevent disbanding of the aggregates; the aggregation curve is thus one of progressive decline (Fig. 1*C*).

It is thus possible to account for (1) the increased responsiveness to ADP of guinea-pig platelets; (2) the peculiar shape of the aggregation curves; (3) the apparent greater stability of ADP in the presence of aggregated platelets, on the basis of the hypothesis that ADP-induced aggregation of guinea-pig platelets is associated with the release of an aggregating substance from these platelets. Assuming the release of such a substance, the question is raised as to its identity. ADP is the only known physiological substance which directly causes platelets to aggregate. In those species where platelets are induced to aggregate by epinephrine and 5-HT[14,15], thrombin[16], collagen[17], tri-ethyl-tin[18], latex particles[19] and fatty acids[20], evidence indicates that such aggregation is caused by ADP released from platelets as a result of their interaction with these agents. Guinea-pig platelets did not aggregate in response to epinephrine or to 5-hydroxytryptamine. It thus seems likely that if an aggregating substance is released from guinea-pig platelets it has a direct aggregating action, and may, therefore, be ADP. Spaet and Zucker[13] were unable to detect release of ADP from human platelets which had been caused to aggregate by addition of ADP; this is in accord with the shape of the aggregation curve obtained with human platelets[2].

I thank Miss Martha Williams and Mrs. Diane Konick for their technical assistance.

AGGREGATION OF RABBIT AND GUINEA-PIG PLATELETS BY OXIME ESTERS

By DR. JAY W. CONSTANTINE and DR. F. A. HOCHSTEIN

Departments of Pharmacology and Medicinal Chemistry, Medical Research Laboratories, Chas. Pfizer and Co., Inc., Groton, Connecticut

PLATELET aggregation induced by thrombin[1,2], fatty acids[2], collagen[3] and latex particles[4] is possibly the result of the action of these substances in causing the release from platelets of the aggregating agent adenosine diphosphate (ADP)[6]; indirect evidence suggests that the same mechanism may be responsible for aggregation induced by epinephrine and 5-hydroxytryptamine[6], and tri-ethyl-tin[7]. It has now been found that 2-acetylfuran methoxycarbonyloxime (2-AFMO) induces aggregation of rabbit and guinea-pig, but not of rat platelets; results of investigation of the action of this and related compounds on platelet aggregation are reported here.

The preparation of platelet-rich plasma from male New Zealand white rabbits and the use of Born's[8] turbidimetric method of investigating platelet aggregation have been described[9]. Platelet-rich plasma from male Hartley guinea-pigs and Sprague–Dawley rats was prepared as described for the rabbit. Platelet-poor plasma was prepared by centrifugation of platelet-rich plasma at 10,000*g* for 20 min. Compounds were dissolved in 0·154 M sodium chloride solution and added in a volume of 0·04 ml. to 4·0 ml. of plasma except where noted otherwise. All concentrations are those of the compounds in plasma. Experiments were performed at room temperature (23° C), except where noted otherwise.

2-AFMO (5×10^{-4}–5×10^{-5} M) caused a decrease in the optical density of rabbit and guinea-pig platelet-rich but not of platelet-poor plasma, in which a stirrer was

rotated at 1,000 r.p.m. The optical density of platelet-rich plasma was not changed by the addition of 2-AFMO in the absence of stirring. Clumps appeared when 2-AFMO was added to stirred platelet-rich plasma, but not when it was added to platelet-rich plasma without stirring, or to platelet-poor plasma. The clumps were identified as platelet aggregates by microscopic observation. Stirring platelet-rich plasma did not cause detectable clumping or significant decrease in optical density. On the basis of these results, it is concluded that the decrease in optical density of stirred platelet-rich plasma in the presence of 2-AFMO was due to platelet aggregation induced by the compound.

Platelet aggregation induced by 2-AFMO in rabbit and guinea-pig platelet-rich plasma was proportional to the concentration of the compound, and at lower concentrations the aggregates began to disperse in less than 5 min (Figs. 1 and 2). The extent of platelet aggregation in response to a given concentration of the compound varied somewhat with different pools of platelet-rich plasma. Following the addition of 2-AFMO to platelet-rich plasma, there was a delay of 40–60 sec before the platelets aggregated (Figs. 1 and 2). This delay in the response occurred consistently in all samples of rabbit and guinea-pig platelet-rich plasma, and at all concentrations at which the compound was tested. The shapes of the aggregation curves obtained with guinea-pig platelets were similar to those previously obtained when guinea-pig platelets aggregated in response to added ADP[10]. Near-threshold concentrations of 2-AFMO resulted in a decrease in optical density followed by a return to the initial level in approximately 5 min (Fig. 2*A*). Slightly higher concentrations of 2-AFMO resulted in a biphasic aggregation curve (Fig. 2*B*). Still higher concentrations of 2-AFMO induced a progressive decline in optical density (Fig. 2*C*). Even with the higher concentrations of 2-AFMO, the optical density returned to, or near, the initial level within 30 min following the addition of 2-AFMO. 2×10^{-3} M 2-AFMO did not induce aggregation of rat platelets in six different pools of platelet-rich plasma.

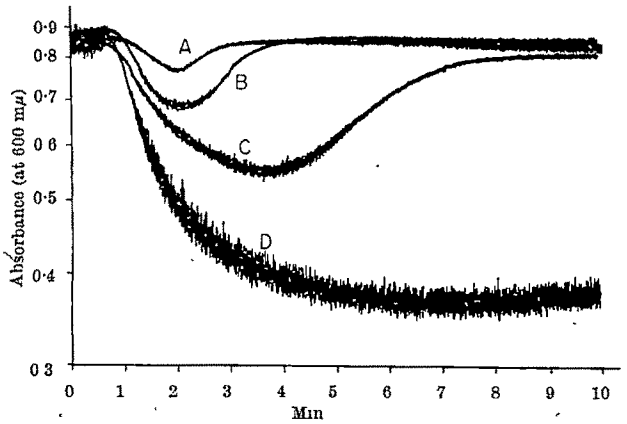

Fig. 1. Changes in optical density of rabbit platelet-rich plasma caused by 2-acetylfuran methoxycarbonyloxime (2-AFMO), added at zero time. (*A*), 5×10^{-5} M, (*B*), 1×10^{-4} M; (*C*), 2×10^{-4} M; (*D*), 4×10^{-4} M

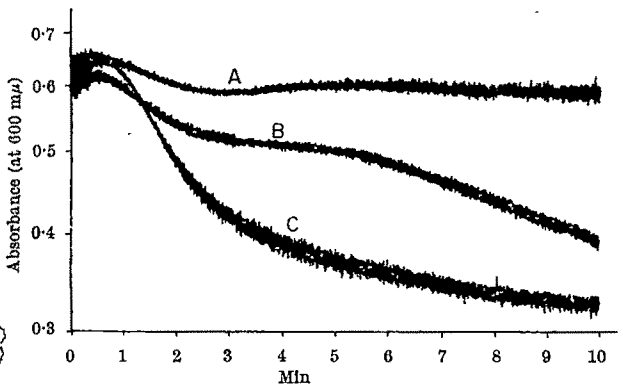

Fig. 2. Changes in optical density of guinea-pig platelet-rich plasma caused by 2-AFMO added at zero time: (*A*), 6×10^{-5} M; (*B*), 8×10^{-5} M; (*C*), 1×10^{-4} M

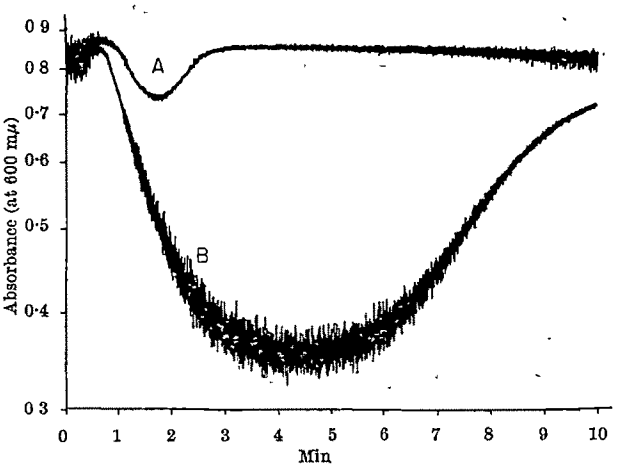

Fig. 3. Changes in optical density of rabbit platelet-rich plasma caused by 2-AFMO (2×10^{-4} M) alone, and in the presence of adenosine (1×10^{-5} M). 2-AFMO added at zero time to plasma which had been incubated 10 min with: (*A*), adenosine, (*B*), 0·154 M sodium chloride solution

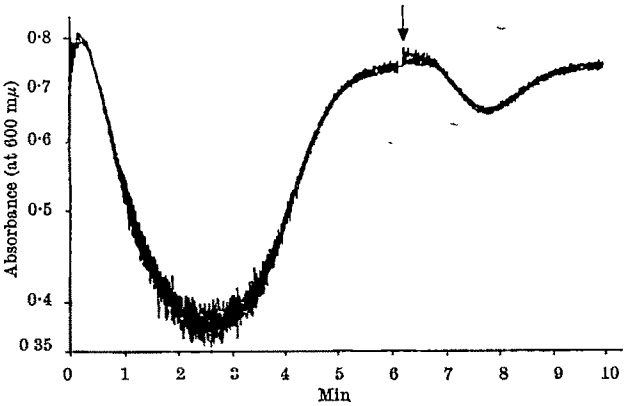

Fig. 4. Changes in optical density of rabbit platelet-rich plasma caused by ADP (1×10^{-6} M) added at zero time, and by 2-AFMO (2×10^{-4} M) added at ↓

10^{-5} M adenosine inhibited aggregation of rabbit platelets induced by 2×10^{-4} M 2-AFMO (Fig. 3). This inhibition was surmountable by a tenfold increase in concentration of the aggregating agent. The aggregation of guinea-pig platelets induced by 10^{-4} M 2-AFMO was not inhibited by 10^{-5} M adenosine. Following spontaneous reversal of strong aggregation of rabbit platelets induced by 2×10^{-4} M 2-AFMO, a second addition of the compound at the same concentration caused only slight aggregation. Following reversal of strong aggregation of rabbit platelets caused by 10^{-6} M ADP, only slight aggregation was induced by 2×10^{-4} M 2-AFMO (Fig. 4); conversely, weak aggregation was caused by 10^{-6} M ADP when it was added to rabbit platelet-rich plasma following the reversal of strong aggregation induced by 2×10^{-4} M 2-AFMO (Fig. 5).

Control responses to 2×10^{-4} M 2-AFMO and to 10^{-6} M ADP were obtained with rabbit platelet-rich plasma (Fig. 6). 2×10^{-3} M 2-AFMO was incubated in platelet-rich and in platelet-poor plasma for 5 min at 23° C, without stirring. Samples of 0·4 ml. from each were then tested for platelet aggregating activity in separate 4·0 ml. portions of platelet-rich plasma. The sample from platelet-poor plasma caused barely detectable platelet aggregation after a delay of about 60 sec, but that from the platelet-rich plasma caused strong platelet aggregation (Fig. 7); moreover, the latter occurred virtually immediately, in contrast to the typical delay which preceded aggregation

induced by 2-AFMO when this was added directly to the control sample of platelet-rich plasma (Fig. 6). The loss of activity of 2-AFMO following its incubation in rabbit platelet-poor plasma was further investigated. Platelet-poor plasma was heated for 30 min at 60° C, followed by centrifugation to remove coagulated protein. 2×10^{-3} M 2-AFMO was then incubated in a sample of the clear supernatant for 5 min at 23° C; another sample of the supernatant was similarly incubated with 0·154 M sodium chloride solution. When 0·4 ml. of the 2-AFMO incubation mixture was added to 4·0 ml. rabbit platelet-rich plasma, strong platelet aggregation occurred after a delay of approximately 60 sec. A 0·4 ml. portion of the sodium chloride incubation mixture did not cause platelet aggregation.

Compounds related to 2-AFMO were investigated in rabbit platelet-rich plasma for aggregating activity, and for inhibition of ADP- and 2-AFMO-induced platelet aggregation. 2-Acetylfuran, 2-acetylfuran oxime, acetone *o*-benzoyloxime, and 3-carbomethoxyisoxazole-5-aldehyde-acetyloxime, each at 5×10^{-4} M, did not induce platelet aggregation, nor did they inhibit aggregation induced by 10^{-6} M ADP or by 5×10^{-4} M 2-AFMO. 2-Acetylfuran acetyloxime, like 2-AFMO, induced aggregation of rabbit platelets; the concentration range which resulted in proportional responses was 5×10^{-4}–5×10^{-5} M.

Gaarder *et al.*[5] demonstrated that ADP causes aggregation of human platelets. Other agents have since been found to induce aggregation of platelets of some, but not all, the species in which they have been investigated. For example, epinephrine, norepinephrine and 5-hydroxytryptamine (5-HT) induce aggregation of human platelets, whereas rabbit platelets are not responsive to the catecholamines, and their behaviour to 5-HT is not predictable[11]; it has recently been reported that guinea-pig platelets are not aggregated by epinephrine or by 5-HT[10]. In contrast to this species difference in responsiveness of platelets to these amines, ADP causes aggregation of platelets of all species which have been investigated. As mentioned earlier, there is evidence to support the hypothesis that aggregation in response to the addition to platelet suspensions of agents other than the nucleotide is mediated by ADP released from platelets as a consequence of their interaction with these agents (refs. 1–4, 6, 7).

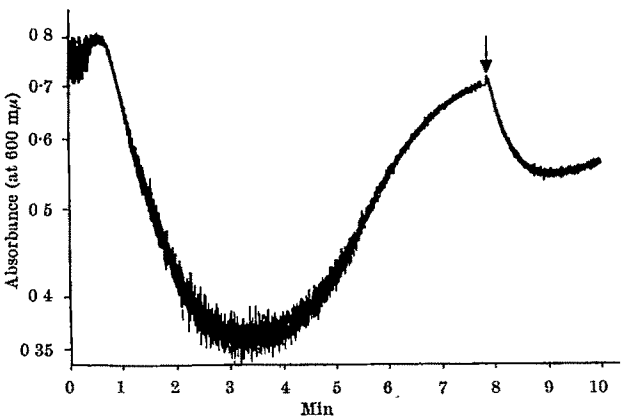

Fig. 5. Changes in optical density of rabbit platelet-rich plasma caused by 2-AFMO (2×10^{-4} M) added at zero time, and by ADP (1×10^{-6} M) added at ↓

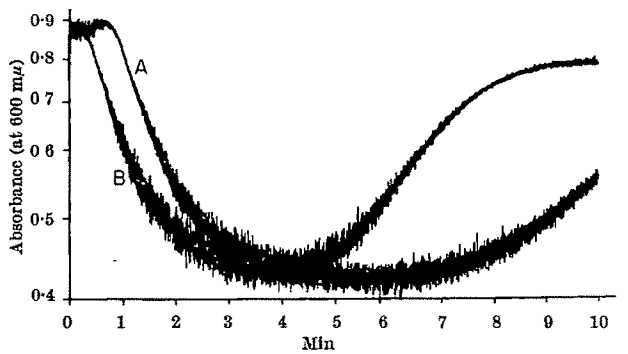

Fig. 6. Changes in optical density of rabbit platelet-rich plasma caused by: (*A*), 2×10^{-4} M 2-AFMO; (*B*), 1×10^{-6} M ADP. Compounds added at zero time. Plasma samples used in experiments illustrated by this figure and by Fig. 7 were taken, for each experiment, from the same pool of plasma

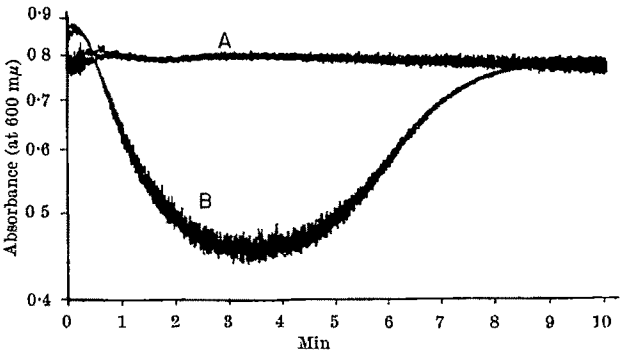

Fig. 7. Changes in optical density of rabbit platelet-rich plasma caused by 0·4 ml. samples of: (*A*), rabbit platelet-poor plasma, (*B*), rabbit platelet-rich plasma, both of which had been incubated 5 min with 2-AFMO (2×10^{-3} M) then added to 4·0 ml. platelet-rich plasma at zero time

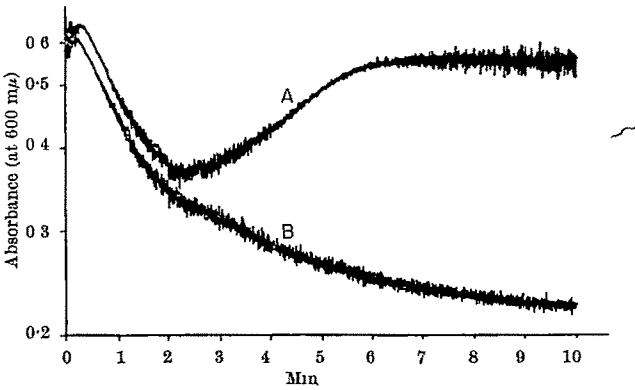

Fig. 8. Changes in optical density of guinea-pig platelet-rich plasma caused by ADP (2.5×10^{-7} M) added at zero time, followed 2 min later by: (*A*), 10^{-3} M hydroxylamine·HCl, (*B*) 0·154 M sodium chloride solution

It is possible that the aggregation of rabbit and guinea-pig platelets induced by 2-AFMO is mediated by ADP released from the platelets. 2-AFMO-induced aggregation of rabbit platelets was inhibited by adenosine, which, as Born and Cross[12] first demonstrated with human plasma, and Regoli and Clark[13] then showed with rabbit plasma, inhibits ADP-induced platelet aggregation. But adenosine did not inhibit 2-AFMO-induced aggregation of guinea-pig platelets; it has been reported that adenosine fails to inhibit aggregation of guinea-pig platelets caused by ADP[10]. Further implication of ADP as the mediator is provided by the observation that rabbit platelet-rich but not platelet-poor plasma, following incubation with 2-AFMO, contained an aggregating factor which, like ADP, acted without the delay in onset of aggregation which was characteristic of 2-AFMO when it was added directly to stirred platelet-rich plasma. The weak response of rabbit platelets to 2-AFMO when this was added following reversal of aggregation caused by ADP, and vice versa, resembles the response of rabbit platelets to repeated additions of ADP[9]. These results do not establish that 2-AFMO-induced platelet aggregation is mediated by ADP released from platelets but they are compatible with such a mechanism of action.

Rabbit platelets aggregated in the presence of 2-acetylfuran acetyloxime, and at the concentrations investigated this compound was approximately equal in effectiveness to 2-AFMO. Rabbit platelets were not aggregated by 2-acetylfuran oxime, a hydrolysis product common to both aggregating agents, which could form in rabbit plasma as a consequence of its esterase activity[14]. The ineffectiveness of both 2-acetylfuran and its oxime derivative suggested that the oxime ester function was necessary for aggregation. However, both acetone *o*-benzoyloxime and 3-carbomethoxyisoxazole-5-aldehydeacetyloxime were ineffective.

We are not yet able to speculate on the mechanism of interaction of platelets and the oxime esters. Oximes are known to reverse the inhibition of cholinesterase by organophosphorus compounds[15], and hydroxylamine is less active in this respect[16]. We found that hydroxylamine inhibited ADP-induced platelet aggregation in each of the three species investigated in the present study. When 10^{-5} M hydroxylamine was added to platelet-rich plasma 2 min after the addition of ADP, there was immediate cessation of aggregation and dispersal of aggregates. Fig. 8 shows this effect with guinea-pig platelets. It is possible that inhibition by hydroxylamine was due to nucleophilic attack at the terminal phosphate bond of ADP.

We thank Miss Martha Williams and Mrs. Diane Konick for their technical assistance.

POSSIBLE MECHANISM OF AGGREGATION OF BLOOD PLATELETS BY ADENOSINE DIPHOSPHATE

By DR. EDWIN W. SALZMAN, DONALD A. CHAMBERS and LENA L. NERI
Department of Surgery, Harvard Medical School, and Surgical Services, Massachusetts General Hospital, Boston, Massachusetts

ALTHOUGH the ability of adenosine diphosphate (ADP) to produce platelet aggregation has been recognized for several years[1], the mechanism of this reaction has not been defined. Several hypotheses offered to explain this phenomenon have implied platelet binding of the ADP molecule resulting in aggregation through participation of this molecule in an intercellular bridge[2–4] or by alteration of the platelet's surface charge[5,6]. Alternatively, Spaet[7] has proposed an energy-yielding reaction involving breakdown of ADP as the cause of platelet aggregation. Recent experiments in our laboratory have revealed serious objections to these hypotheses and have suggested a different explanation for the action of ADP.

Isotopic experiments utilizing ADP-8-^{14}C and ADP-^{32}P have shown that in citrated platelet-rich plasma there is stepwise dephosphorylation of ADP to AMP and then to adenosine, which is incorporated by the platelet[8]. The dephosphorylation is primarily a plasma reaction and does not require the presence of platelets[7,8]. Since no radioactivity is recovered in the platelets after addition of ADP-^{32}P or AMP-^{32}P, it appears that these compounds do not bind to the platelet but are only incorporated after dephosphorylation. Afterwards the platelet-bound adenosine is rephosphorylated, the ^{14}C label eventually appearing in platelet adenosine triphosphate (ATP)[8].

In platelet-rich plasma, ADP-^{14}C-induced platelet aggregation is regularly accompanied by incorporation of radioactivity by the platelets and is inhibited by agents such as EDTA or arginine methyl ester, which inhibit incorporation of the ^{14}C label[9].

Washed platelets resuspended in heated plasma or in a buffered electrolyte solution aggregate strongly with ADP, if an acid- or ammonium sulphate-precipitate of plasma or serum is added. However, in these systems, platelet incorporation of radioactivity with ADP-^{14}C is strongly inhibited[8]. Thus, the binding of labelled nucleotide is not vital to platelet aggregation by ADP.

The breakdown of ADP to AMP and of AMP to adenosine in platelet-rich plasma is blocked by 0·01 M potassium cyanide (Table 1), which also strongly inhibits the incorporation of radioactivity by platelets after ADP-^{14}C. However, cyanide does not block platelet aggregation but in fact facilitates it and may retard disaggregation (Fig. 1). Thus, breakdown of ADP is not required for platelet aggregation.

Table 1. INHIBITION OF DEPHOSPHORYLATION OF ADP OR AMP BY CYANIDE

	ATP	ADP	AMP	Adenosine
(1) ADP-8-^{14}C	1	10	15	10
(2) ADP-8-^{14}C + 0 01 M potassium cyanide	0	31	2	0
(3) AMP-8-^{14}C	2	2	14	14
(4) AMP-8-^{14}C + 0 01 M potassium cyanide	0	0	33	1

Incubation of 10^{-6} M ADP-8-^{14}C or 10^{-6} M AMP-8-^{14}C in citrated platelet-rich plasma for 10 min at 37° C, followed by extraction with 10 per cent trichloroacetic acid and paper chromatography as previously described (ref. 8). Tracings were obtained by scanning the strips in a Vanguard 880 'Autoscanner', and the curves were identified by comparison with suitable standards and their area measured by planimetry. The figures above represent the area (in cm^2) under each curve.
Results of similar experiments in platelet-free plasma were qualitatively identical, except that no ATP was identified in the extracts.

Previous experiments with ^{14}C- or ^{32}P-labelled ATP have shown that ATP is converted to ADP in plasma and then follows the same degradation pathway outlined above. The dephosphorylation of ATP to ADP is not inhibited by 0·01 M potassium cyanide, but the subsequent breakdown of ADP is blocked (Table 2), and platelet incorporation of radioactivity after incubation with ATP-8-^{14}C is prevented. Aggregation of platelets by

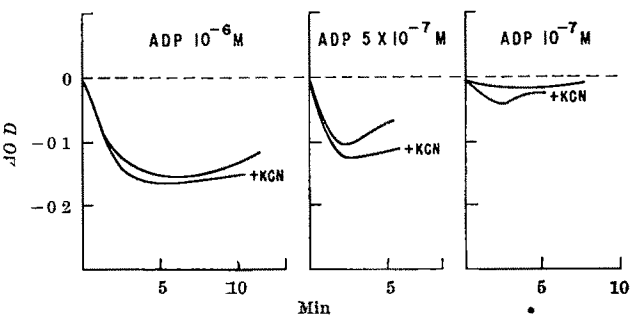

Fig. 1. Platelet aggregation with ADP (turbidimetric technique of Born (ref. 2) and O'Brien (ref. 10)). 0·01 M cyanide facilitates aggregation and, at higher concentrations of ADP, retards disaggregation

ADP is inhibited by preliminary addition of ATP and is reversed by ATP added after maximal aggregation has occurred (Fig. 2). This effect of ATP is not blocked by cyanide. Thus, the inhibition of ADP-aggregation by ATP does not require binding of the ATP molecule to the platelet.

Table 2. EFFECT OF CYANIDE ON DEGRADATION OF ATP

	ATP	ADP	AMP	Adenosine
(1) ATP-8-^{14}C	5	9	17	11
(2) ATP-8-^{14}C + 0·01 M potassium cyanide	10	40	0	0

Incubation of 10^{-6} M ATP-8-^{14}C in platelet-rich plasma and treatment as in Table 1. Similar results were obtained in platelet-free plasma.

The most likely explanation for these observations is the following hypothesis: Platelets require an active energy-supplying metabolic process to remain unsticky, the adhesive form being the low-energy state in a system analogous to the contracted state of striated muscle. Preservation of size and shape of the platelet and other cells requires an active metabolic process. This process involved splitting of ATP to ADP by an ATPase located in the platelet membrane. In the presence of added ADP, the breakdown of ATP by this enzyme is blocked by product inhibition. Addition of ADP to platelet-rich plasma inhibits an active process, disrupting the regulatory membrane system by which platelet 'non-stickiness' is maintained. That ADP causes platelets to swell has been shown by Zucker and Borrelli[11]; it is probable that sphering of the platelet exposes receptive sites on the platelet surface permitting secondary bridging with fibrinogen[12–14] or in appropriate conditions with other proteins[6]. This secondary bridging phenomenon probably involves a divalent cation bond, because it can be split by EDTA. EDTA also produces platelet swelling[15], perhaps by blocking a divalent cation-dependent membrane ATPase.

We have observed strong ATPase activity of intact platelets resuspended in a buffered electrolyte system containing calcium and magnesium (Fig. 3). Similar data have recently been reported by Robinson *et al.*[6], and White and Krivit[17] have localized ATPase activity in the platelet membrane by histochemical techniques. The activity is inhibited by adenosine diphosphate (Fig. 3) but not by 10^{-2} M potassium cyanide or 10^{-3} M ouabain. Very weak activity was also found in a red cell suspension and in platelet-free citrated plasma.

The action of a membrane ATPase which splits substrate ATP on the outer surface of the cell membrane is unusual, but 'ecto-ATPase' activity has been demonstrated in neuroglia and other cells[18]. Furthermore, the platelet is an unusual cell, unique in its origin as a cytoplasmic fragment with an external surface that was originally buried within the cytoplasm of the megakaryocyte. The activity of the calcium–magnesium-dependent membrane ATPase of platelets is depressed by temperature decrease, which is also known to cause platelets to swell[15] and to aggregate[19]. It is possible that

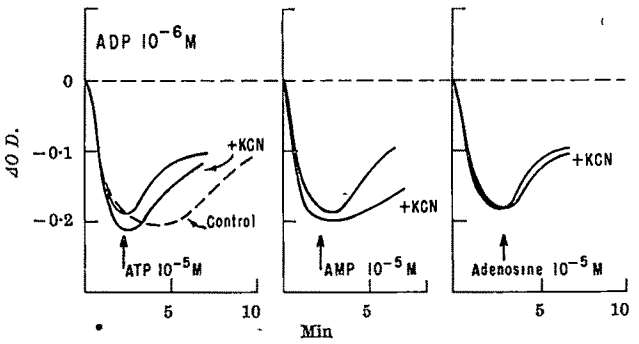

Fig. 2. Disaggregation by ATP, AMP, and adenosine of platelets aggregated by ADP. The effect of AMP is prevented by 0·01 M cyanide; the effect of ATP and of adenosine is not

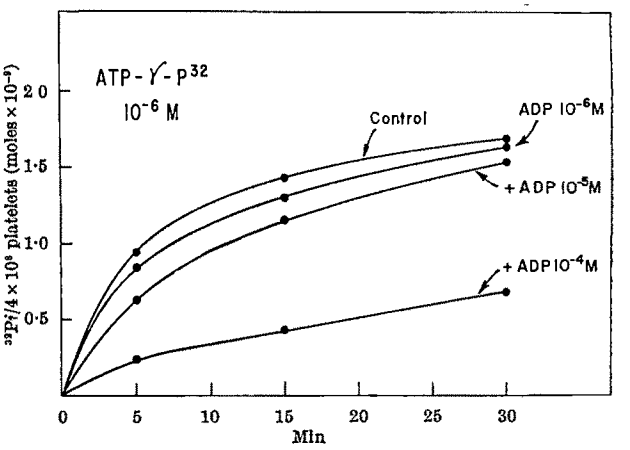

Fig. 3. Release of inorganic phosphorus-32 from ATP-γ-^{32}P. Washed platelets were re-suspended in Ringer's solution containing 1/10 volume of 3·8 per cent tri-sodium citrate and 0·005 M magnesium chloride, buffered to pH 7·5, and were incubated at 20° with 2×10^{-9} moles of ATP-γ-^{32}P. After the reaction was stopped with trichloroacetic acid, inorganic phosphate was determined by a modification of the method of Martin and Doty (ref. 16)

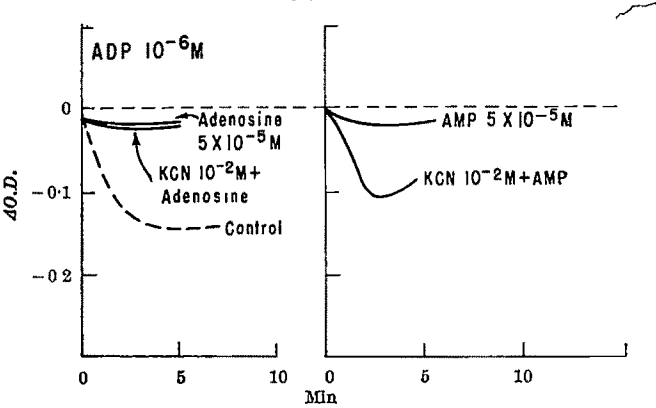

Fig. 4. Inhibition of ADP-induced platelet aggregation by AMP and adenosine added 10 min before the ADP. The inhibitory effect of AMP is impaired by cyanide; the effect of adenosine is not

this enzyme is thrombosthenin, a calcium–magnesium dependent ATPase isolated by Bettex-Galland and Lüscher[20] from an unknown locus in platelets. The known contractile properties of this protein could account for the change of platelet shape and development of stickiness resulting from the addition of ADP.

It is likely that disaggregation following aggregation produced by ADP results from degradation of ADP, which allows membrane ATPase activity to resume. Increasing temperature favours disaggregation[10] by favouring dephosphorylation of ADP by plasma enzymes and by increasing the membrane ATPase activity.

The inhibitory effect of ATP on platelet aggregation can be explained by its role as the natural substrate for the postulated membrane ATPase. One might argue that ATP could inhibit or reverse platelet aggregation by complexing ionized calcium. This explanation is unlikely, for we found citrate, which has calcium complexing ability equal to that of ATP[21], to be 100 times less potent than ATP as an inhibitor of ADP action.

Adenosine is known to inhibit ADP-induced platelet aggregation, and this effect increases with time[2]. It is not blocked by cyanide (Fig. 4). When added to ADP-aggregated platelets, adenosine causes them to disaggregate (Fig. 2), a reaction which is not opposed by cyanide. 0·01 M potassium cyanide is a very weak inhibitor of the incorporation of adenosine-^{14}C by platelets[8].

AMP inhibits the aggregating effect of ADP[2] and causes disaggregation when added to ADP-clumped platelets (Figs. 4 and 2), but these effects are blocked by cyanide, which blocks conversion of AMP to adenosine and prevents platelet incorporation of radioactivity after AMP-^{14}C

is added to platelet-rich plasma. It appears that AMP must be converted to adenosine before it can inhibit platelet aggregation in response to ADP. ADP, AMP and adenosine or their degradation products apparently compete for sites on the platelet[8], and it has been proposed[2] that this accounts for the inhibition of ADP-induced platelet aggregation by AMP and adenosine. Alternative explanations are possible, such as one which involves synthesis of ATP from platelet adenosine, a reaction which is not blocked by cyanide and which might be expected to favour the membrane ATPase reaction described here and to increase with time, as does the inhibitory effect of adenosine and AMP. This platelet synthesis of ATP from adenosine is not blocked by 5×10^{-4} M 2,4-dinitrophenol (ref. 8) and therefore probably occurs by a route other than oxidative phosphorylation.

In summary, this hypothesis is proposed for further study. Addition of adenosine diphosphate to platelet-rich plasma leads to breakdown of the ADP through stepwise dephosphorylation to adenosine which is then incorporated into the platelets. This reaction is not crucial to platelet clumping but is probably important for ultimate dispersal of the platelet aggregate. The presence of ADP in the platelet environment inhibits the splitting of ATP to ADP, a reaction which otherwise occurs through platelet membrane ATPase, the function of which is customarily to keep the platelet in an unsticky state and to maintain the cell size and shape. Inhibition of this ATPase by its normal product, ADP, leads to exposure of adhesive sites and permits platelet aggregation through intermedate secondary bridges containing calcium, fibrinogen, or other proteins.

EFFECT OF TRYPSIN ON *Escherichia coli* AND RABBIT RETICULOCYTE RIBOSOMES

By DR. R. ZAK*, PROF. K. G. NAIR and PROF. MURRAY RABINOWITZ†

Departments of Medicine, Biochemistry and Physiology, and the Argonne Cancer Research Hospital‡, University of Chicago, Chicago, Illinois

WE have previously reported experiments which suggest that ribosomal aggregates from heart muscle are stabilized by interaction between nascent peptide chains[1]. Treatment of the ribosomal assemblage with a proteolytic enzyme, either chymotrypsin or trypsin, as well as with ribonuclease is required to release monomers; neither enzyme alone is completely effective. Similar results have been reported for the chick embryo polysomes that synthesize collagen[2], and for the ribosomal aggregates isolated from lymph nodes that are active in γ globulin synthesis[3]. Myofibrillar proteins, collagen and γ globulin are all composed of sub-units having a strong tendency for spontaneous interaction. It was concluded, therefore, that an interaction between newly synthesized polypeptide chains might in certain circumstances contribute to the stability of polysomes.

Liver and reticulocyte polysomes, in contrast to those from muscle, connective tissue and lymph nodes, are completely converted to monomers, or into Mg^{2+}-stabilized dimers, by ribonuclease treatment[4,5]. Moreover, Williamson and Schweet have shown that treatment of ribosomes from reticulocytes with puromycin leads to the release of peptide chains but not to breakdown of the ribosome aggregate unless energy is added[6]. Since mild trypsin treatment of liver[1,7,8] and reticulocyte[8] polysomes also leads to their breakdown, it would appear that proteolytic enzymes affect the ribonucleoprotein complex not only by causing the release of nascent peptide chains, but also by an effect on the structure of the ribosomes.

To determine the means whereby proteolytic enzymes alter the state of aggregation of ribosomes, a systematic investigation of the effect of mild proteolysis on ribosomal structure and function was undertaken. It is the purpose of this article to report the results of that investigation. Relatively mild tryptic digestion caused an inhibition of the binding by ribosomes of polyuridylic acid. Perhaps, secondary to this effect, the binding of aminoacyl-*s*RNA to ribosomes and the incorporation of ^{14}C-labelled amino-acid into protein were also inhibited. Trypsin also caused a dissociation of *E. coli* and reticulocyte monomers into their sub-units; trypsin-treated sub-units failed to recombine to form 70*S* particles when incubated in the presence of an adequate concentration of magnesium. The results of trypsin treatment of ribosomes and polysomes emphasize the importance of the protein moiety of the ribosome in the binding of artificial, and probably also of natural, messenger RNA, and in the Mg^{2+}-requiring association of ribosomal sub-units. Trypsin appears then to disrupt polysomes not only by removal of nascent peptide chains, but also by disturbing the aminoacyl-*s*RNA- ribosome-*m*RNA[9] complex through damage to the ribosomal protein.

E. coli strain *B* was grown in an enriched medium[10] and collected in the exponential phase of growth. Ribosomes were isolated, pre-incubated and washed as described by Nirenberg and Matthaei[11]. Reticulocytes were obtained from anaemic New Zealand albino rabbits by cardiac puncture after treatment of the animals with 2·5 per cent phenylhydrazine. The polyribosomes and monomers were isolated according to the method of Arnstein *et al.*[12].

Assay of the binding of ^{14}C-phenylalanyl-*s*RNA to ribosomes was carried out with 'Millipore' membrane filters as described by Nirenberg and Leder[13]. The 70*S* ribosomes and the 50*S* sub-units adhere quantitatively to the membrane, but approximately 30 per cent of the 30*S* sub-units pass through. Determination of incorporation of ^{14}C-phenylalanine into protein by ribosomes was according to the method of Nirenberg and Matthaei[11]; incorporation was terminated by the addition of 5 per cent

Table 1. EFFECT OF TRYPSIN ON BINDING AND INCORPORATION OF ^{14}C-PHENYLALANYL-*s*RNA BY *E. coli* AND RABBIT RETICULOCYTE RIBOSOMES

Experiment	*E. coli*			Rabbit reticulocytes					
				Monomers			Polysomes		
	Control (c.p.m.)	Trypsin (c p.m)	Decrease (%)	Control (c p.m.)	Trypsin (c.p.m.)	Decrease (%)	Control (c.p.m.)	Trypsin (c.p.m)	Decrease (%)
^{14}C-PHENYLALANYL-*s*RNA									
Binding	981	578	42	1,703	598	65			
Release	665	639	4	332	199	40			
INCORPORATION OF ^{14}C-PHENYLALANINE									
Without poly U	139	117	21	190	139	27	2,460	980	60
With poly U	5,126	527	90	5,442	685	88	5,417	1,006	82

E. coli ribosomes were pre-incubated for 45 min at 35° C with the complete system for assaying amino-acid incorporation into protein[11]. The medium (medium I) used to measure ^{14}C-phenylalanyl-*s*RNA binding to ribosomes contained in 0 1 ml.: 2–4 × 10^3 c.p.m. ^{14}C-phenylalanyl-*s*RNA; 10 μmoles *tris*-HCl buffer *p*H 7·6; 2 μmoles magnesium acetate; 8 μmoles ammonium chloride; and 20 μg polyuridylic acid. Incubation was for 15 min at 35°. The medium (medium II) used to assay ^{14}C-phenylalanine incorporation into protein by *E. coli* ribosomes contained 0·1 ml.: 5 × 10^4 c.p.m. ^{14}C-phenylalanine; 5 μmoles *tris*-HCl buffer *p*H 7 6, 1 5 μmoles magnesium chloride; 5 μmoles potassium chloride; 0·75 μmoles mercaptoethanol; 0·1 μmole ATP; 0 2 μmole phosphoenolpyruvate; 0·025 μmole GTP; 2 5 μg pyruvate kinase; 0·1 mg *E. coli* 105,000*g* supernatant protein; and 20 μg polyuridylic acid when indicated. For ^{14}C-phenylalanine incorporation into protein by reticulocyte ribosomes, the system was the same except that the magnesium chloride concentration was 8 mM; 10 mM glutathione was used in place of the mercaptoethanol; and 1 mg of reticulocyte '*p*H 5 enzymes' was used. Incubation was for 15 min at 35° when ribosomal nomomers were used and 5 min at 35° C when polysomes were used. In each assay, approximately 2 $O.D_{260}$ mμ of ribosomes were present. Results are expressed as c.p m. of ^{14}C-phenylalanine bound or incorporated per $O.D_{260}$ mμ of ribosomes in 30 min at 0° C. To test for release of bound ^{14}C-phenylalanyl-*s*RNA, trypsin treatment followed incubation with ^{14}C-phenylalanyl-*s*RNA. The values are the average of duplicate determinations.

Table 2. A COMPARISON OF THE ABILITY OF *E. coli* RIBOSOMES TO SYNTHESIZE ^{14}C-POLYPHENYLALANINE AFTER TRYPTIC TREATMENT IN THE PRESENCE OR ABSENCE OF PREVIOUSLY ADDED ^{14}C-PHENYLALANYL-*s*RNA AND POLY U

System	C.p.m./$O.D_{260}$	Decrease (%)
Ribosomes (control)	2,148	
Ribosomes pre-treated with trypsin, then ^{14}C-Phe-*s*RNA and poly U added	1,101	51·5
Ribosomes (control)	1,930	
Ribosomes incubated with ^{14}C-Phe-*s*RNA and poly U first, then trypsin treated	915	52·5

^{14}C-phenylalanyl-RNA and polyuridylic acid were bound to *E. coli* ribosomes either before or after trypsin treatment as indicated. The incubation conditions for binding were as in Table 1. Trypsin was added at a concentration of 0 5 μg/$O.D_{260}$ ribosomes and the reaction terminated, after incubating for 30 min in ice by a three-fold excess of soybean trypsin inhibitor.

Ribosomes thus pretreated were incubated for a second time in a mixture containing energy and 105,000*g* supernatant enzymes (medium II, Table 1) for 10 min at 35° C

trichloroacetic acid, and 1 mg of bovine serum albumin was added. The specific circumstances of the experiments are given in Tables 1 and 2 and Figs. 1 and 2. The precipitate was washed with cold and hot trichloroacetic acid on a 'Millipore' membrane filter. The membranes and the protein were dissolved in Bray's solution and radioactivity was determined with 49 per cent efficiency in a 'Tricarb' liquid scintillation counter.

Trypsin and soybean trypsin inhibitor were purchased from Worthington Biochemical Corporation; ^{14}C-labelled and non-radioactive polyuridylic acid were purchased from Miles Chemical Corporation; ^{14}C-L-phenylalanine, having a specific activity of 333 mc./mmole, was obtained from New England Nuclear Corporation. *E. coli* stripped *s*RNA (General Biochemicals) was charged with ^{14}C-phenylalanine and nineteen ^{12}C-amino-acids[14]; the product had a specific activity of 1–1·6 × 10^5 c.p.m./mg *s*RNA.

Treatment of ribosomes with 5 μg trypsin for 30 min at 0° C leads to the release of less than 0·3 per cent of 280 mμ absorbing material. (In each case the concentration of trypsin is in μg of enzyme per optical density unit (at 260 mμ) of ribosomes.)

The effect of trypsin on the following ribosomal properties was studied: (1) the dissociation of monomers into sub-units; (2) the reassociation of sub-units; (3) the binding and release of ^{14}C-polyuridylic acid; (4) the binding and release of ^{14}C-phenylalanyl-*s*RNA; (5) the incorporation of ^{14}C-phenylalanine into protein. In each of the tests the effect of trypsin was completely blocked by the prior addition of a three-fold excess of soybean trypsin inhibitor. Neither trypsin inhibitor nor DFP trypsin caused a change in ribosome function. No ribonuclease activity was detectable in the trypsin.

(1) *Dissociation of monomers into sub-units.* There was no appreciable breakdown of *E. coli* ribosomes to 50*S* and 30*S* sub-units when treated for 30 min at 0° C with 0·5–5 μg of trypsin (Fig. 1*A*), or for 5 min at 25° (Fig. 2). When 10 μg of trypsin was used, however, the 70*S* peak was somewhat decreased in height and broadened, indicating slight breakdown of 70*S* particles (Fig. 1*A*, curve 3). Rarely, a ribosomal preparation was unusually sensitive to trypsin, and complete disruption into 50*S* and 30*S* sub-units occurred with 2 μg trypsin.

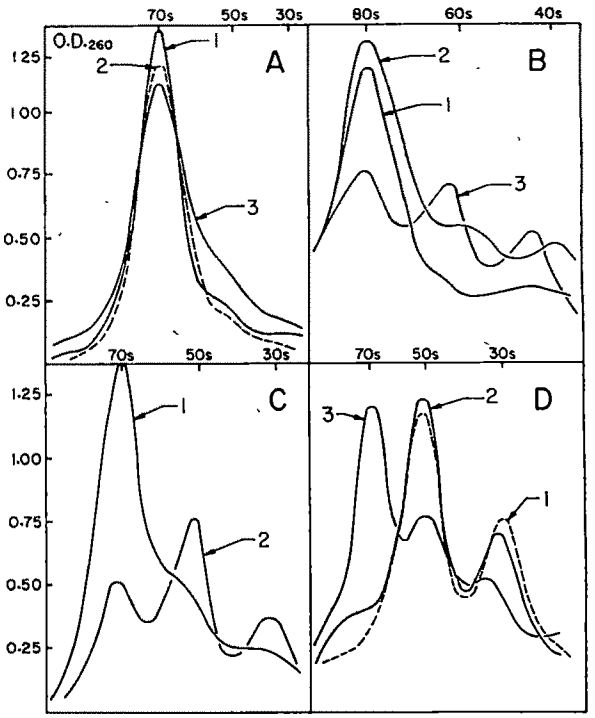

Fig. 1. Sucrose gradient centrifugation of ribosomes treated with trypsin. The concentration of ribosomes is given as the absorption at 260 mμ. A 0·1-ml. portion of ribosomes containing 2–3 $O.D_{260}$ mμ was analysed on a 5–20 per cent linear sucrose gradient prepared with the same buffer as that in which the ribosomes were suspended. The gradient was centrifuged at 39,000 r.p.m. in the *SW* 39 rotor of the model *L*2 Spinco centrifuge for 90 min at 0°. The sedimentation profiles were recorded with a Gilford spectrophotometer, model 2000. Ribosomes or ribosomal sub-units were exposed to trypsin for 30 min at 0°, following which soybean inhibitor was added in three-fold excess. *A*, *E. coli* ribosomes: curve 1, control; curve 2, treated with 0 5 μg trypsin/$O.D_{260}$ mμ; curve 3, treated with 10 μg trypsin/$O.D_{260}$ mμ. *B*, Reticulocyte monomers purified by differential centrifugation: curve 1, control; curve 2, treated with 0·7 μg trypsin/$O.D_{260}$ mμ; curve 3, treated with 10 μg trypsin/$O.D_{260}$ mμ. *C*, Dissociated and reassociated *E. coli* ribosomes. Ribosomes were dissociated by dialysis for 3 h against 5 × 10^{-3} M *tris*-HCl buffer *p*H 7·3, 10^{-4} M magnesium chloride, and were reassociated by overnight dialysis against 5 × 10^{-3} N *tris*-HCl buffer *p*H 7·3, 1·75 × 10^{-2} M magnesium chloride, 8·6 × 10^{-2} M potassium chloride, and 6 × 10^{-3} mercaptoethanol. Trypsin treatment followed re-association. Curve 1, No trypsin treatment; curve 2, treatment with 5 μg trypsin/$O.D_{260}$mμ *D*, Effect of tryptic treatment on reassociation of 50*S* and 30*S* sub-units. Curve 1, *E. coli* ribosomes dissociated into 50*S* and 30*S* sub-units by dialysis against low Mg^{2+}; curve 2, 50*S* and 30*S* sub-units treated with 5 μg trypsin/$O.D_{260}$ mμ followed by re-association; curve 3, 70*S* ribosomes treated with 5 μg, trypsin/$O.D_{260}$ mμ followed by dissociation and re-association

The 'trypsin resistant' ribosomes could be transformed into 'sensitive' ones by dissociating them to sub-units in 10^{-4} M Mg^{2+}, and then reassociating the sub-units in 10^{-2} M Mg^{2+}. The reconstituted ribosomes were extremely sensitive to trypsin, as little as 0·5 μg of enzyme now causing their dissociation (Fig. 1*C*). The reason for this is not clear; it may have been the result of the release of a ribosomal component (*m*RNA, *s*RNA or the nascent peptide chain) during dissociation; or the sub-units may not reassociate in a manner identical to their original structure.

(2) *Reassociation of sub-units.* Trypsin-treated ribosomes may be dissociated by dialysis against a low concentration of Mg^{2+}, and reassociated to 70*S* particles by dialysis against buffer containing 10^{-2} M Mg^{2+} (Fig. 1*D*, curve 3). The reassociation was, however, 20–30 per cent less complete when the ribosomes had been treated with trypsin (compare Fig. 1*D*, curve 3, with Fig. 1*C*, curve 1). If instead of the 70*S* monomers the sub-units obtained by dialysis were exposed to trypsin, no reassociation occurred (Fig. 1*D*, curve 2). The sub-units were far more sensitive to tryptic digestion than the intact ribosome, perhaps because the association to form 70*S* monomers

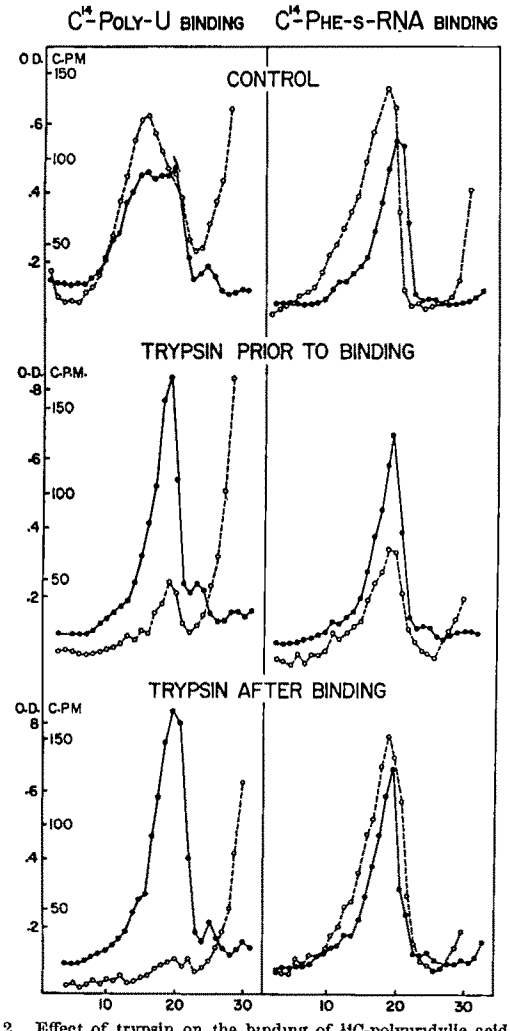

Fig. 2. Effect of trypsin on the binding of ^{14}C-polyuridylic acid and ^{14}C-phenylalanine-*s*RNA to *E. coli* ribosomes. The ribosomes were prepared as described in Table 1. The conditions for assay of the binding of ^{14}C-polyuridylic acid to ribosomes were identical to those of Suarez and Nathans[19]. The 0·2 ml. reaction mixture contained 2×10^4 c.p.m. of ^{14}C-polyuridylic acid (specific activity 0·183 μc./mg), and 7 $O.D._{260}$ mμ of ribosomes. The conditions for measuring the binding of ^{14}C-phenylalanyl-*s*RNA to ribosome were described in Table 1. Ribosomes were treated with 5 μg of trypsin per $O.D._{260}$ mμ for 5 min at 25° C, and 15 μg of trypsin inhibitor was then added. Density gradient centrifugation was carried out as described in Fig. 1. The tubes were punctured and 10-drop fractions were collected and processed as described before[1]. ●—●, Optical density at 260 mμ; ○ - - - - ○, c.p.m.

partly protects the sites required for cohesion of the sub-units.

Similarly, 70*S* ribosomes isolated from *Streptococcus pyogenes*[15] and liver[16] are relatively resistant to ribonuclease, but become sensitive to the enzyme when dissociated to their sub-units.

Reticulocyte ribosomes react to trypsin treatment in a manner similar to that of *E. coli* ribosomes except that they are more sensitive to the enzyme. As little as 0·7 μg of trypsin at 0° C for 30 min causes considerable increase in the numbers of 60*S* and 40*S* particles (Fig. 1*B*). Yeast ribosomes also are split into sub-units by treatment with papain for 12 min at 37° C (ref. 17).

(3) *Binding and release of ^{14}C-polyuridylic acid.* The binding of ^{14}C-polyuridylic acid to *E. coli* 70*S* ribosomes was decreased by 75 per cent after treatment with 5 μg of trypsin for 5 min at 25° C (Fig. 2). The results accord with those of Kaji and Kaji[18]. The ^{14}C-polyuridylic acid bound to 70*S* ribosomes by incubation for 20 min at 0° C was completely released by treatment with trypsin. The amount of ^{14}C-polyuridylic acid bound to *E. coli* ribosomes was not affected by the presence of aminoacyl *s*RNA. Furthermore, the addition of aminoacyl *s*RNA (20 μg *s*RNA per $O.D._{260}$) did not prevent the trypsin-induced release of polyuridylic acid from the ribosome. Trypsin did not alter the sedimentation (7*S*) of ^{14}C-polyuridylic acid in a linear sucrose density gradient.

(4) *Binding and release of ^{14}C-phenylalanyl sRNA.* Treatment of 70*S* ribosomes from *E. coli* with 0·5, 5 or 10 μg of trypsin caused a decrease in the polyuridylic acid directed binding of ^{14}C-phenylalanyl-*s*RNA to the ribonucleoprotein particles (Table 1 and Fig. 2*A*). Analysis of the ribosomes on sucrose gradients disclosed that the decrease in binding of ^{14}C-phenylalanine-*s*RNA occurred even though less than 10 per cent of the ribonucleoprotein particles were split into sub-units. Ribosomes from *E. coli* and reticulocyte were treated with trypsin and centrifuged in a sucrose gradient; the 70*S* particles isolated from the gradient showed a reduction of ^{14}C-phenylalanyl-*s*RNA binding similar to that of the whole preparation. Thus, the inhibition by trypsin of the binding of aminoacyl-*s*RNA to ribosomes does not seem to be solely a consequence of the formation of sub-units.

When *E. coli* ribosomes to which aminoacyl-*s*RNA was bound were treated with 0·5 or 5·0 μg of trypsin, no release of radioactivity occurred (Table 1, Fig. 2).

Trypsin decreased the amount of ^{14}C-phenylalanyl-*s*RNA bound to reticulocyte monomers, as was also the case with *E. coli* ribosomes (Table 1). About 40 per cent of the ^{14}C-phenylalanyl-*s*RNA bound to reticulocyte ribosomes was removed by subsequent treatment with 5 μg trypsin in contrast to the results obtained with *E. coli* ribosomes (Table 1).

The effect of trypsin on ^{14}C-phenylalanyl-*s*RNA binding and on ^{14}C-polyuridylic acid binding to ribosomes was not of the same degree. Although the binding of charged *s*RNA required polyuridylic acid, trypsin doses which result in more than an 80 per cent reduction of polyuridylic acid binding led to only a 50 per cent decrease in *s*RNA binding. Moreover, trypsin caused the release of all the polyuridylic acid bound to ribosomes from *E. coli*, whereas little or no charged *s*RNA was liberated. The results may be accounted for by transfer of the aminoacyl *s*RNA from a ribosomal site requiring polyuridylic acid to another site where it is bound directly to the ribosome. A binding site of this type has been suggested by Nirenberg and Leder[13].

(5) *Incorporation of ^{14}C-phenylalanine into protein.* Incorporation of ^{14}C-phenylalanine into protein by either *E. coli* or reticulocyte ribosomes was greatly impaired by trypsin treatment (Table 1). The stimulation by polyuridylic acid of phenylalanine incorporation into protein by ribosomal monomers was nearly abolished by trypsin, as might have been predicted from the fact that the enzyme

effected a decrease in the binding of polyuridylic acid. The incorporation of ^{14}C-phenylalanine into reticulocyte polysomes containing natural messenger RNA is affected to a lesser degree (Table 1). Trypsin had less effect on the incorporation of ^{14}C-phenylalanine into monomers in the absence of polyuridylic acid. It would appear that the attachment of natural messenger to ribosomes is more resistant to trypsin than is polyuridylic acid. Trypsin was still effective when ^{14}C-phenylalanyl-*s*RNA and polyuridylic acid were added prior to the proteolytic enzyme (Table 2).

The experiments indicate that the binding of polyuridylic acid to ribosomes is markedly diminished by alteration or removal of one or more ribosomal peptides. The proteolytic treatment was mild, as indicated by the unchanged sedimentation constant and the absorption ratio (280 mμ : 260 mμ) of the monomers. To what extent the ribosome protein participates in the binding of polyuridylic acid and natural messenger RNA is not known. It is possible that a specific configuration or structure of the ribosomal protein is required for the binding of messenger RNA to the ribosomal RNA. Had the prior association of polyuridylic acid and *s*RNA with the ribosome protected against proteolytic destruction of the binding site, this possibility would have been reinforced.

There was less reduction of ^{14}C-phenylalanyl-*s*RNA binding to ribosomes by trypsin than, and may well be secondary to, the inhibition of polyuridylic acid binding. The binding of that aminoacyl *s*RNA to ribosomes is dependent on the presence of natural or artificial *m*RNA. The release of template RNA from the ribosome could then secondarily cause the loss of aminoacyl *s*RNA. The observation that ^{14}C-phenylalanyl *s*RNA bound to ribosomes in the presence of polyuridylic acid is not released by tryptic digestion despite the release of bound polyuridylic acid is difficult to explain. The aminoacyl *s*RNA may be transferred to another binding site which is not dependent on the presence of polyuridylic acid. Although the effect of trypsin on phenylalanyl-*s*RNA binding can be adequately explained as secondary to a decrease in polyuridylic acid binding, an additional effect on ribosomal structure to alter an aminoacyl RNA binding site cannot be ruled out.

Similarly the inhibition of ^{14}C-phenylalanine incorporation into protein by trypsin could be secondary to the effect of the enzyme on the binding and release of polyuridylic acid. If so, the inhibition by trypsin of amino-acid incorporation into protein observed with reticulocyte polysomes, and with *E. coli* and reticulocyte monomers, suggests that natural *m*RNA is also released by proteolytic action. The polyuridylic acid directed amino-acid incorporation of ^{14}C-phenylalanine was in all cases more sensitive to tryptic action than incorporation directed by natural messenger. Thus, natural *m*RNA bound to ribosomes may be more resistant to release by trypsin than is bound polyuridylic acid. Possibly, this is an example of more effective protection of those binding sites from tryptic digestion by the bound *m*RNA than by polyuridylic acid.

An additional site of action of tryptic digestion is required to account for the enhanced formation of sub-units from *E. coli* ribosomes. It also appears that the peptide configuration required for this Mg^{2+}-linked association of sub-units is exposed when ribosomes are dissociated into 50*S* and 30*S* sub-units. These sub-units are much more sensitive to tryptic digestion than are 70*S* ribosomes.

The disruption of polyribosomes from *E. coli* or reticulocytes by proteolytic enzymes would seem then to be the result of an alteration of the binding site for *m*RNA; the *m*RNA is released and then the ribosomal assemblage breaks down. Inasmuch as complete dissociation of *E. coli* and reticulocyte ribosomes was obtained by ribonuclease, it is unnecessary to postulate an interaction between nascent polypeptide chains for the stabilization of the polyribosomes. The failure of proteolytic enzymes to affect the polysomal structure from rabbit skeletal muscle reported by Breuer *et al.*[20] may be due to a relative insensitivity of the messenger binding site in that preparation.

However, where ribonuclease does not completely disrupt the polyribosomal structure, as in the case of the ribosomes concerned with the synthesis of myofibrillar protein, collagen or γ globulin, it is possible that an interaction between ribosomal-bound polypeptide chains containing the sub-units of the protein participates in stabilization of the structure.

We thank Margaret Scott and Mai-hwa Chen Tu for their invaluable technical help.

TRANSPIRATION RESISTANCE AND ENERGY BUDGET OF *Populus sargentii* LEAVES

By DAVID F. PARKHURST* and DAVID M. GATES

Institute of Arctic and Alpine Research, University of Colorado, Boulder

THE energy budget of a plant leaf is intimately coupled to the leaf temperature and resulting physiology including photosynthesis, respiration, transpiration and other processes. The transpirational loss of water represents a loss of energy and is therefore part of the energy budget of a leaf. The energy budget may be written as follows, if storage and metabolic energy are neglected:

$$Q_{abs} = R_l + C - LE \quad (1)$$

where Q_{abs} = total amount of solar, skylight, and thermal radiation absorbed by the leaf; R_l = re-radiation from the leaf surface; C = convection from the leaf to the air; L = latent heat of vaporization of water, a quantity which is slightly temperature-dependent and the units of

* This work was carried out while the senior author was a participant in the Undergraduate Research Program in Engineering at the University of Colorado, Boulder.

which are cal g^{-1}; and E = transpiration rate. Each of these quantities may be evaluated from the following relationships:

$$R_l = \varepsilon \sigma T^4 \text{ cal cm}^{-2} \text{ min}^{-1} \quad (2)$$

where T_l is the leaf temperature; σ is the Stefan–Boltzmann radiation constant and ε is the emissivity of the leaf surface, taken to be 0·97.

$$C = 6{\cdot}5 \times 10^{-3} (V/D)^{1/2} (T_l - T_a) \text{ cal cm}^{-2} \text{ min}^{-1} \quad (3)$$

where V is the wind speed in cm sec^{-1}; D is the significant leaf dimension in the direction of air flow, in cm; T_l is the leaf temperature; and T_a is the air temperature in °C.

$$E = \frac{{}_s d_l(T_l) - d_a(T_a)}{R} \text{ g cm}^{-2} \text{ min}^{-1} \quad (4)$$

where ${}_s d_l(T_l)$ is the density of water vapour at the mesophyll cell walls lining the substomatal cavity of the leaf assuming saturation at the leaf temperature T_l, $d_a(T_a)$ is the density of water vapour in the free air in g cm^{-3}, and R is the diffusion resistance of the leaf to water vapour in min cm^{-1}. This equation can be rewritten in terms of the relative humidity (r.h.) of the air, and the water vapour density of the air at saturation ${}_s d_a(T_a)$:

$$E = \frac{{}_s d_l(T_l) - \text{r.h.}_s d_a(T_a)}{R} \text{ g cm}^{-2} \text{ min}^{-1} \quad (5)$$

The assumption that the mesophyll cell walls lining the substomatal cavity are saturated with water may be incorrect. If the water content is below saturation within the substomatal cavity then the calculated value of R is larger than the true value and it must then be recognized that only an 'apparent, or fictitious' resistance is determined. However, the apparent resistance is useful if saturation is assumed whenever it is reintroduced into equation (5) to compute a transpiration rate. Also, the apparent resistance will be related rather closely to the actual resistance.

For a leaf in its natural environment, the energy budget, equation (1), is constantly solved by adjustments in leaf temperature and transpiration rate. For given environmental conditions—air temperature, relative humidity, wind speed, and radiation intensity—the transpiration resistance of a leaf governs how freely the leaf transpires and thereby determines whether the leaf temperature is relatively high or low. Once the transpiration resistance of a leaf is known, then the energy budget equations can be solved to give the predicted leaf temperature and transpiration rate for any given environmental conditions. Conversely, by measuring the leaf temperature and evaluating the energy budget for the leaf, one can show that a measured transpiration rate is a valid, actual rate. This will be demonstrated by the observed results.

In this investigation we observed the transpiration rate of leaves from a *Populus sargentii* tree and from this determined the diffusion resistance of the leaves by solving for R in equation (5). Each leaf was excised from the branch with its petiole under water to prevent air from blocking the tracheids. It was then sealed into a potometer chamber, and placed in the test chamber of a controlled-environment wind tunnel, where it was subjected to a steady wind speed and illumination. The temperature and relative humidity of the air were continuously monitored, and by threading a 40-gauge thermocouple through the leaf we also recorded the leaf temperature. The leaf surface was in each case at an angle of 45° to the wind direction. The light source was a 650-W '*DWA*' movie lamp.

The transpiration resistance, leaf temperature, air temperature, T leaf − T air, relative humidity, and the various components of heat loss from the leaf, are shown in the figures for four different leaves. In theory, the net radiation absorbed should remain constant with time, and thus the net heat loss should also be constant. In the figures a slight upward trend can be seen, and small fluctuations occur in the net heat loss term. The upward trend results from a tendency of the wind tunnel to become heated with use; its walls grow warmer and the thermal radiation load on the leaf increases accordingly. The fluctuations may have occurred as the storage term varied about zero, or they may have been due in part to experimental error in reading the potometer.

Fig. 1 shows an example of the typical behaviour of leaves observed in this investigation. The light was filtered by 10 cm of water to remove most of its heat; the result at the surface of the leaf was 2,120 ft.-candles of visible light with only 0·32 cal cm^{-2} min^{-1} net radiation from the lamp.

The initial low value of resistance may have been caused by uptake as the petiole and leaf cells adjusted to the osmotic concentration of the incoming tap water. Note that while the air temperature was greater than the leaf temperature, the value of (T leaf − T air) follows the resistance quite closely. Thus, when resistance is highest, transpiration is lowest and the temperature difference is algebraically at its highest (near zero). When the resistance drops, transpiration increases, and (T leaf − T air) drops to a low value (near − 3° C). Note also that because the leaf is cooler than the air, the convection term is actually a heat gain for the leaf, and is a negative heat loss. The steep drop in transpiration resistance at about 1,030 occurred, of course, as the stomates opened.

The leaf of Fig. 2 was illuminated with 313 ft.-candles, but since the light was not filtered, the heat load from the lamp was 1·1 cal cm^{-2} min^{-1} at the surface of the leaf. Because of the higher incoming radiation, this leaf was warmer than the air and the convection term was positive. Note that the (T leaf − T air) difference was positive, and that for this case also it increased and decreased with the resistance.

For leaves under low illumination, the resistance tended to vary erratically as in the example of Fig. 3. This leaf received 35 ft.-candles from the lamp, and 0·4 cal cm^{-2}

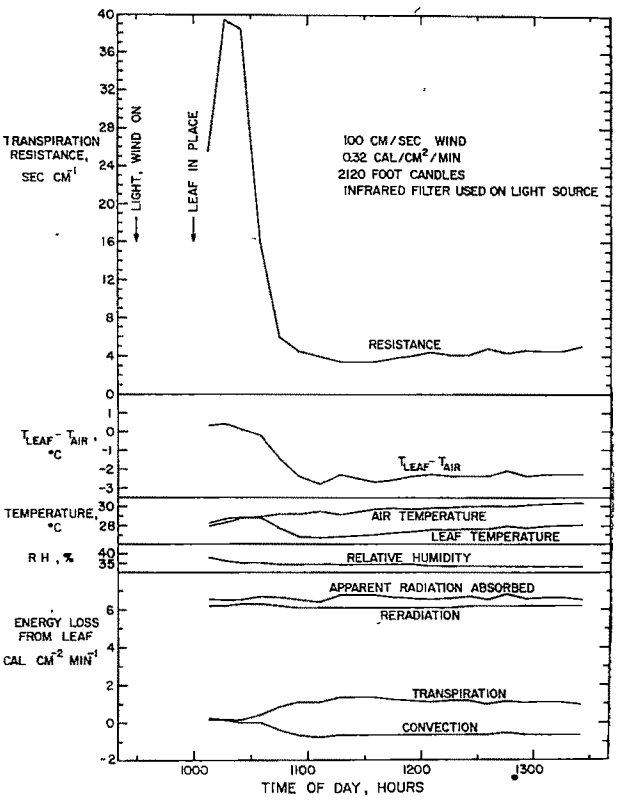

Fig. 1. Energy parameters for a cottonwood leaf under high illumination and low thermal radiation

min^{-1} at its surface. The transpiration rate was sufficient to keep the leaf temperature below that of the air, and the convection term was therefore negative.

Data for the most interesting leaf observed are presented in Fig. 4. It behaved normally until about 1520 hours, but then its resistance began to oscillate with increasing amplitude. It is striking that, while the convection and transpiration terms of the energy balance varied widely, the net energy loss remained fairly constant (within limits, as already discussed). This was so even though the leaf temperature was also quite variable.

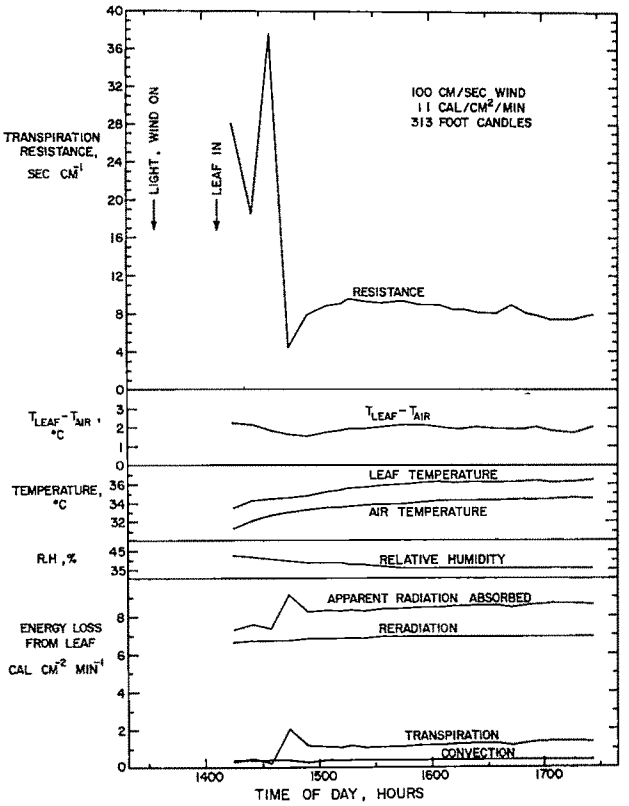

Fig. 2. Energy parameters for a cottonwood leaf under moderate illumination and high thermal radiation

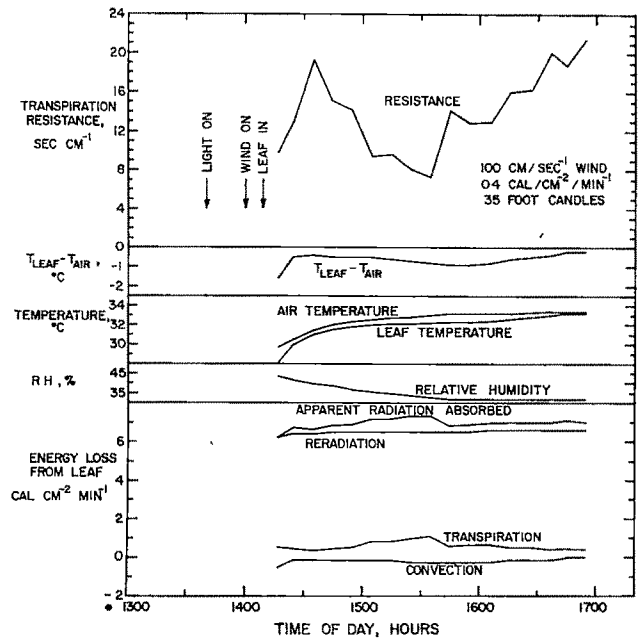

Fig. 3. Energy parameters for a cottonwood leaf under low illumination and low thermal radiation

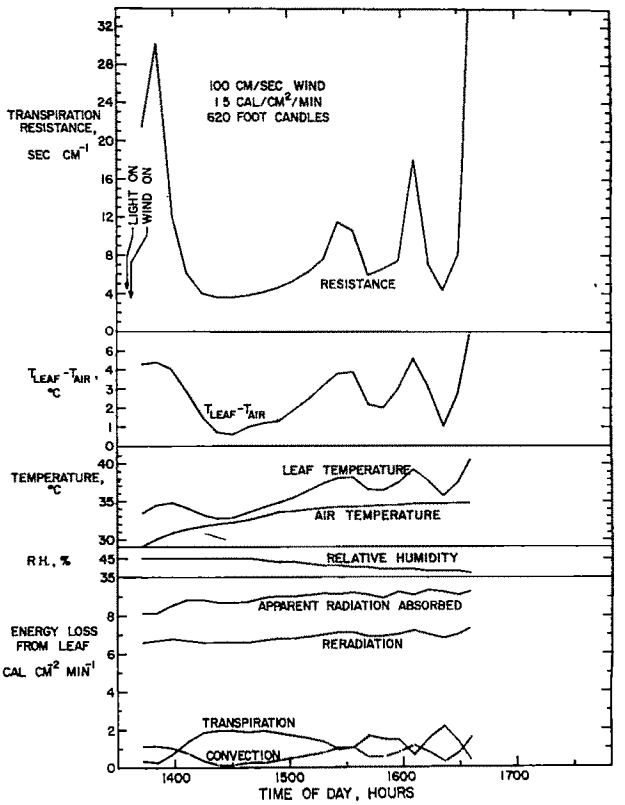

Fig. 4. Energy parameters for a cottonwood leaf under moderate illumination and high thermal radiation

The oscillatory nature of the transpiration, apparent resistance, and leaf temperature is somewhat puzzling. The fact that the leaf temperature changed simultaneously with the transpiration rate indicates that the observed transpiration was a real loss of water from the leaf. We do not profess to understand entirely what occurred here. It could have been related to the osmotic potential within the leaf and guard cells as modified by the water into which the leaf was placed for the experiment. It could have been a problem of water transport in which the leaf first dried out, the guard cells lost turgor, the stomatal opening decreased, and then water flow increased, guard cell turgor was restored, and the stomata reopened. Transpiration may next have increased, drying occurred, and the cycle repeated itself.

It is possible that the phenomenon can be explained in terms of temperature as it affects photosynthesis, respiration, and carbon dioxide concentration in the guard cells. It should be noted that the leaf temperature was not very high at first, for example 33°–35° C, at which temperature net photosynthesis was still very favourable. After the oscillation in transpiration began, however, the leaf temperature varied from 36° to 40° C, which was high enough to considerably reduce net photosynthesis and increase respiration[1]. However, purely on the basis of the processes of photosynthesis, respiration and temperature change it is difficult to postulate a feedback mechanism which could cause the oscillations.

In summary, we can say that well-lit leaves from *Populus sargentii* have an apparent transpiration resistance of about 4 sec cm^{-1}. This can be used to solve the energy budget equation for a given leaf. The resistance may be higher, and unpredictable, for a shade leaf.

We thank Prof. Frank Kreith, of the Department of Mechanical Engineering, for his generous help. This work was supported in part by a U.S. National Science Foundation grant to D. M. Gates.

AUTORADIOGRAPHIC DEMONSTRATION OF CHOLESTEROL FILTRATION AND ACCUMULATION IN ATHEROMATOUS RABBIT AORTA

By DR. C. W. M. ADAMS and R. S. MORGAN
Department of Pathology, Guy's Hospital Medical School, London

PREVIOUS autoradiographic studies have indicated that the inner part of the rat aortic wall labels more rapidly than does the outer part after intravenous injection of tritium-labelled cholesterol[1]. This evidence was taken to show that cholesterol enters the aorta from the blood and flows from the inner to the outer part of the wall of the vessel. This view was confirmed by showing that the inner part of the rabbit aorta labelled very rapidly after the vasa vasorum (adventitial vessels) had been stripped off the vessel, but 8–16 days elapsed before the outer part labelled strongly[2]. The tritium label apparently did not dissociate from cholesterol during the experiment, as was shown by the complete recovery of plasma radioactivity from the cholesterol fraction[2].

The present investigation was undertaken to determine the fate of labelled cholesterol in rabbit atheromatous aorta. Eight young New Zealand white rabbits were fed a diet enriched with 1 per cent cholesterol[3] for 6 weeks; they were then injected intravenously with 2·0 mc. of tritium-labelled cholesterol. This amount of radioactive cholesterol was one hundred times greater than that administered in a previous investigation of the aorta in the cholesterol-fed rabbit[4]. The cholesterol for injection was prepared by dissolving 16 mc. of cholesterol–*T*(*G*) (Radiochemical Centre, Amersham) in 8 ml. of ethanol containing 0·5 per cent 'Tween 20'; this solution was evaporated under nitrogen and redissolved in 8 ml. of physiological saline[5]. The animals were killed at intervals of 1–20 days after injection; in the meantime they were maintained on the cholesterol-enriched diet. Plasma lipid radioactivity at the time of killing was estimated in an acetone–ethanol (1 : 1 v/v) extract of plasma with a liquid scintillation counter. Autoradiographs of transverse sections of the aortic arch were prepared by our previous method[2], but the exposure time was increased to 5 weeks.

Little exchange was apparent between infiltrated labelled cholesterol and sterol previously deposited in the atheromatous plaque (as can be seen by comparison of Figs. 1 and 2), yet entry of cholesterol into the atheromatous aortic wall was more rapid and resulted in heavier labelling than that found in our previous studies on the normal rat[1,2] and rabbit[2] aorta.

Granule counts were made in eight radial bands of autoradiographs of each vessel; a total area of about 0·1 sq. mm was counted in each aorta. Counts for the inner and outer half of the media are recorded as histograms (Fig. 3). These results clearly show that the atheromatous plaque labelled more rapidly than did the tunica media after injection of ^{3}H–cholesterol. An exception occurred two days after injection, when radioactivity was slightly higher in the outer media and inner plaque than in the inner media and outer plaque (Fig. 3). The greater labelling in the outer media at this stage may have been due to entry of isotope from the vasa vasorum, before ^{3}H–cholesterol had penetrated from the lumen into the middle part of the aortic wall.

This general pattern of labelling is consistent with the major entry of cholesterol into the aortic wall being from the lumen of the vessel. Nevertheless, it could be argued that this pattern is merely a reflexion of the rate of incorporation of ^{3}H–cholesterol into the different layers of the aorta. However, we have shown above that there is little dynamic exchange between radioactive cholesterol and sterol previously deposited in the atheromatous plaque (Figs. 1 and 2), so the rapid labelling of the plaque cannot be attributed to exchange with the large mass of cholesterol in the lesion. There is no reason to suppose that the rates of intracellular incorporation and intercellular deposition of cholesterol in the plaque would be greater than that in the undegenerated tunica media if both regions were equally exposed to the same 'hypercholesterolaemic' milieu. In fact it is likely in such circumstances that greater intracellular incorporation would occur in the tunica media than in the plaque, because the cell population is higher in the former than the latter. If this postulate is valid, it follows that the rate of incorporation or deposition of cholesterol in the various layers of the aorta is not primarily determined in

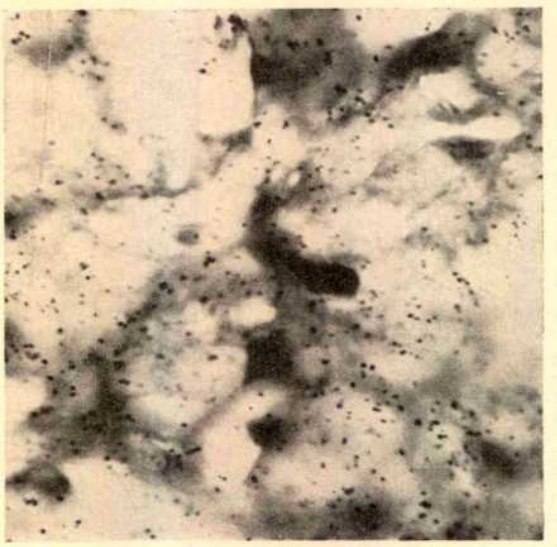

Fig. 1. Autoradiograph of atheromatous aortic intima in rabbit 20 days after injection of 2·0 mc. of ^{3}H–cholesterol (×*c.* 1,575)

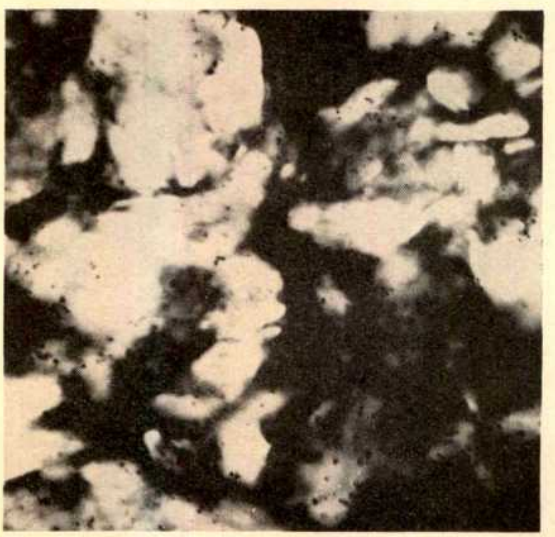

Fig. 2. Same field as Fig. 1 but photographed in polarized light, so that cholesterol crystals are birefringent (white) but autoradiograph granules remain black. Note that the cholesterol crystals previously deposited in the atheromatous intima are only trivially labelled

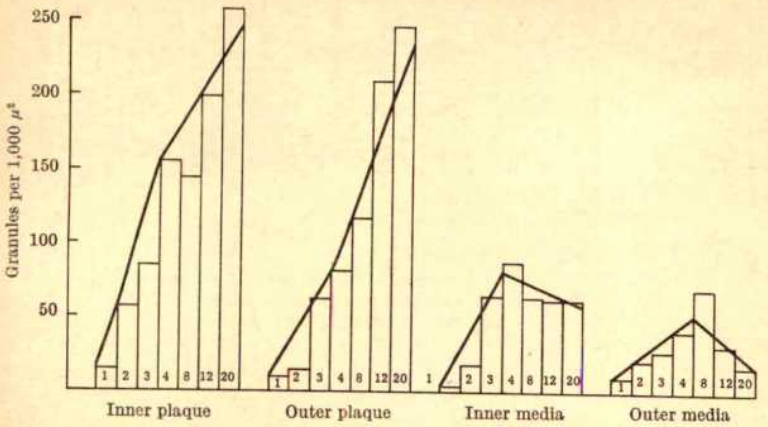

Fig. 3. Histogram of autoradiographic granule counts (less background) in atheromatous rabbit aorta after intravenous injection of 2·0 mc. of ^{3}H–cholesterol. Note the initial fast labelling of the inner plaque, followed by heavy labelling of the outer plaque and inner media, while the outer media labels slowly. The numbers at the base of each column represent days after injection. The heavy line is a guide to the overall change in radioactivity in the different aortic layers, but it has no mathematical significance

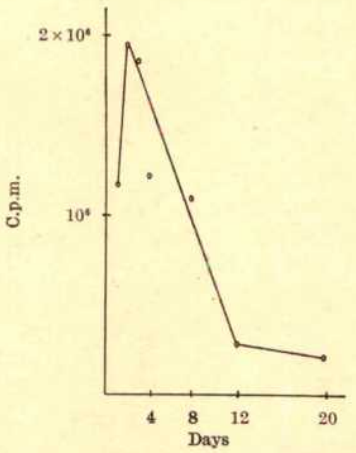

Fig. 4. Plasma lipid radioactivity (c.p.m./1·0 ml. plasma) in cholesterol-fed rabbits after intravenous injection of 2 mc. of ^{3}H–cholesterol

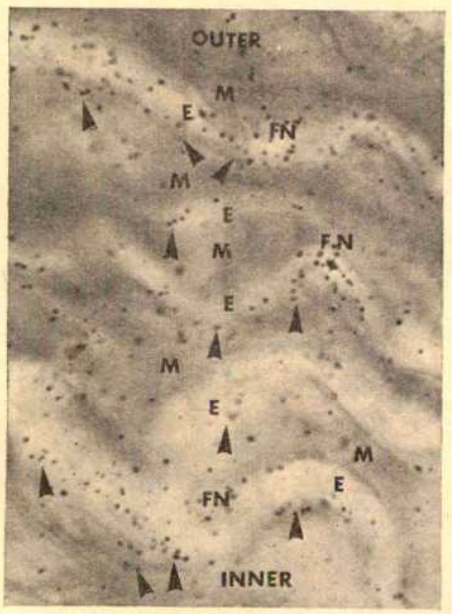

Fig. 5. Autoradiograph of inner media of atheromatous rabbit aorta 2 days after injection of 2 mc. of ^{3}H–cholesterol. Note accumulation (arrows) of label on inside of elastic laminae (*E*) and diffusion through probable fenestrations (*FN*) in the laminae; *M*, smooth muscle fibres. (×*c.* 1,575)

the young animal by metabolic differences between the cells of these layers, but is directly related to the rate of entry of cholesterol into each zone. The rate of outward transfer is exceeded when a certain rate of entry is attained, so that the excess cholesterol (overload) is deposited in that region. Thus, the quantity of cholesterol that is deposited would be directly proportional to the extent to which the rate of entry exceeds that of transfer. Studies on the fate of 4–^{14}C–cholesterol in both rabbit and cockerel aorta suggest in fact that the cholesterol overload in the inner zones may be quite small in relation to cholesterol transfer[6,7].

Plasma lipid radioactivity remained high in the initial period of the experiment but fell after 8 days (Fig. 4). The pattern of rise and fall of radioactivity in the outer media is similar to that in the blood, but is somewhat delayed; it is presumably due either to slow passage of cholesterol through the aortic wall or to relatively rapid dynamic exchange between such cholesterol in passage and steroid in the connective tissues of the tunica media. The progressive increase of radioactivity in the plaque indicates that cholesterol is both entering and being retained in the lesion. Radioactivity in the inner media maintained its level from the eighth day of the experiment onwards. This equilibrium was probably a result of deposition of cholesterol in the innermost region of the media balanced by loss of steroid by outward diffusion.

These observations are consistent with our previous hypothesis[1,2,8] that cholesterol in the blood normally filters through the arterial wall from the intima to the adventitia and with physiological evidence that metabolites and plasma constituents diffuse through arterial and capillary walls[9–13]. This view was further supported by the observation in the present investigation that labelled cholesterol occasionally accumulates on the inner side of the aortic elastic laminae (Fig. 5). If the elastic lamina can be regarded as a partial barrier to the filtration of cholesterol, a local concentration of label would be expected to accumulate on the inner side of the lamina when excess cholesterol diffuses outwards through the aortic wall.

The evidence provided by our present and previous autoradiographic investigations suggests that cholesterol diffuses through the normal and atheromatous aortic wall, but it does not indicate whether such diffusing cholesterol is bound to lipoprotein or is dissociated from this transport vehicle[14–16].

This work was partly supported by a grant from the National Heart Institute, National Institutes of Health, Bethesda, Maryland. Fig. 3 was prepared by Miss Pat Archer, Department of Medical Illustration, Guy's Hospital.

GROWTH AND FOOD CONSUMPTION OF LABYRINTHECTOMIZED HAMSTERS DURING CHRONIC CENTRIFUGATION AT 5*g* AND 6*g*

By PROF. CHARLES C. WUNDER, BOSKO MILOJEVIC and LEE EBERLY

Departments of Physiology and Otolaryngology, University of Iowa, Iowa City, Iowa

THROUGHOUT the past 12 years, several laboratories have reported that growth of plants and animals is possible during chronic centrifugation at survivable intensities[1]. At exposure to sufficiently intense fields, growth, though measurable, is slower, and life expectancy is shorter for experimental animals than it is for control animals. The interpretation of most of these reports rests on the assumption that the greater energy demanded to oppose the simulated high gravity diverts food materials ordinarily utilized in growth processes. An alternative explanation is that field gradients and Coriolis accelerations not associated with true gravitational fields can result in disorientation and nausea. Under these conditions, there would be a consequent reduction in growth rate due either to lower food consumption or to lower capacity for food utilization. These non-gravitational effects of centrifugation have suggested difficulties which may be encountered in generating artificial gravity in space stations, in space vehicles, or in supplying a 1*g* environment to control organisms in satellites designed for the study of the biological effects of weightlessness.

The non-gravitational effects of centrifugation are believed to develop in response to the complex stimulation of the vestibular organs. To eliminate such unnatural stimulation, female golden hamsters, *Mesocricetus auratus*, were bilaterally labyrinthectomized at the age of 22 days. The labyrinthectomy was accomplished by surgical approach into the labyrinth through the oval window, followed by aspiration of endolymphatic fluid from the cochlear labyrinth. The tympanum was completely opened. The destroyed labyrinth was filled by topical application of a few drops of streptomycin sulphate (100 mg/c.c.). This operation was performed with forty-fold magnification by means of a Zeiss operating microscope. The animals were anaesthetized with sodium pentobarbital (30 mg/kg body-weight) given intraperitoneally. Surgical details will be described more fully elsewhere. Each experimental animal had three litter-mate control animals: a sham-operated sister which accompanied it during centrifugation, a labyrinthectomized sister which remained at 1*g*, and a sham-operated sister which also remained at 1*g*.

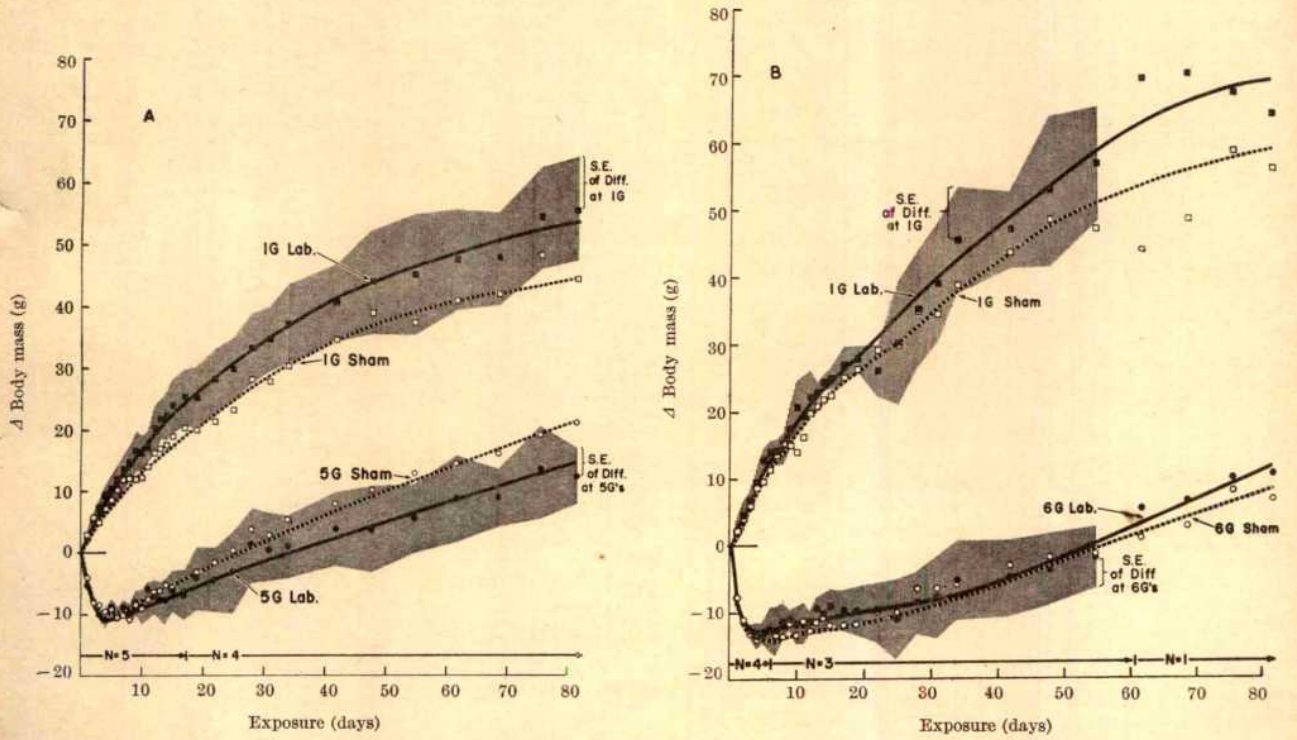

Fig. 1. Growth as measured in terms of change in body mass. *A*, Hamsters at 5*g*. Initial body-weights were 61·78 ± 2·8 g, 59·80 ± 3·59 g, 57·82 ± 1·83 g, and 59·64 ± 2·53 g for labyrinthectomized animals at 5*g*, for sham-operated animals at 5*g*, for labyrinthectomized animals at 1*g*, and for sham-operated animals at 1*g* respectively. Standard errors of differences between animals at same field are indicated. The number *N* of litters (containing one member in each of the four conditions) is indicated. Measurements were discontinued when any member of a litter died. The paired sample errors for differences between labyrinthectomized versus sham-operated animals at a given field are displayed by the height of shading above or below points for labyrinthectomized animals. The tendency for greater mass change among labyrinthectomized control animals could result from the smaller size, and thus greater growth potential, at the onset of the experiment. *B*, Growth of hamsters at 6*g* initial body-weights were 58·75 ± 3·35 g, 63·38 ± 1·46 g, 56·88 ± 3·62 g and 65·40 ± 0·39 g. The notation used is the same as that employed in *A*

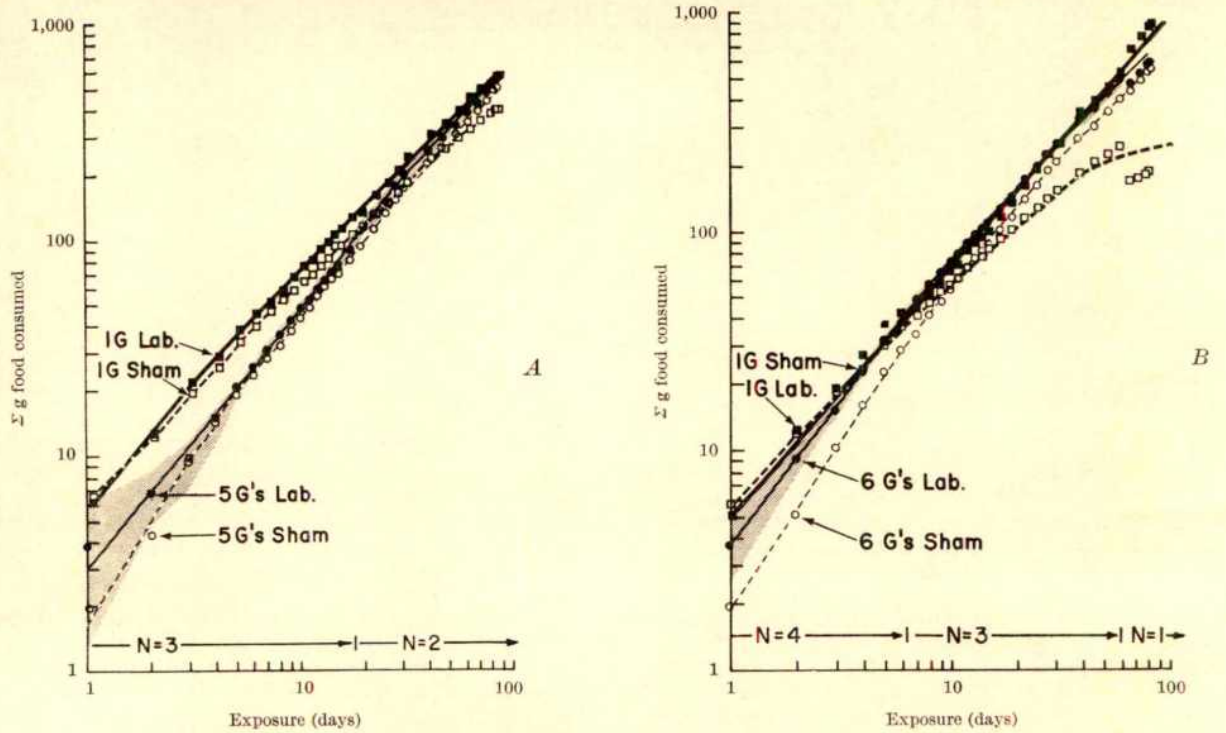

Fig. 2. *A*, Cumulative food consumption for 5*g* animals. The notation used is the same as that for Fig. 1. Standard errors are only shown for differences between animals in centrifuge. *B*, Average cumulative food consumption for 6*g* animals

Sham operations involved surgical puncture of the ear drum under sodium pentobarbital anaesthesia. Except for loss of hearing and loss of gravity reflexes associated with the inner ear in labyrinthectomized animals, all hamsters used in this investigation recovered quickly from surgical trauma and proceeded to develop at 1*g* until 36 days of age. At this time, sham-operated animals (61·79 ± 1·30 g, $N = 18$) were slightly larger than labyrinthectomized animals (58·92 ± 1·30 g, $N = 18$).

Chronic exposure at 5*g* (at a radius of 51 cm at the cage bottom) or 6*g* (radius of 62 cm) at 97 r.p.m. was initiated when animals had achieved 36 days of age. Centrifugation was performed in a modification of a previously described machine[2]. Procedures for exposure were similar to those used in earlier hamster investigations[3]. Each animal was housed in a 5 in. × 8·5 in. × 4 in. compartment where food consisted of Purina 'Laboratory Chow' with uncooked potatoes as the source of water. Exposure was interrupted for a period of 15 min each day for feeding, cage cleaning and mass measurements.

The growth pattern throughout 82 days of exposure was essentially the same as that found with normal centrifuged hamsters[3]. Experimental animals first underwent a loss in body mass, followed by some recovery of mass, with eventual growth in excess of original size but not comparable with that for the 1*g* litter-mate animals (Fig. 1). Cumulative food intakes (Purina 'Laboratory Chow' for hamsters) throughout the experiment were comparable with those of both types of centrifuged hamsters (Fig. 2). When the experiment was discontinued at the end of 89 days of exposure, the general appearance of both types of animals subjected to comparable exposure was quite similar (Fig. 3).

Throughout the first 2 or 3 days of exposure, the sham-operated animals demonstrated a post-rotatory type of nystagmus during observation at normal gravity. This behaviour did not persist throughout the remainder of the experiment. Apparently the animals adjusted by reducing the threshold for gravity and/or rotatory perception. Sham-operated animals removed from the centrifuge after 89 days of exposure did not demonstrate righting reflexes at 1*g*. Similar observations have been performed in this laboratory with kittens[4] and fish[5], which demonstrate righting reflexes only when they were exposed once more to high gravity. Centrifugation is

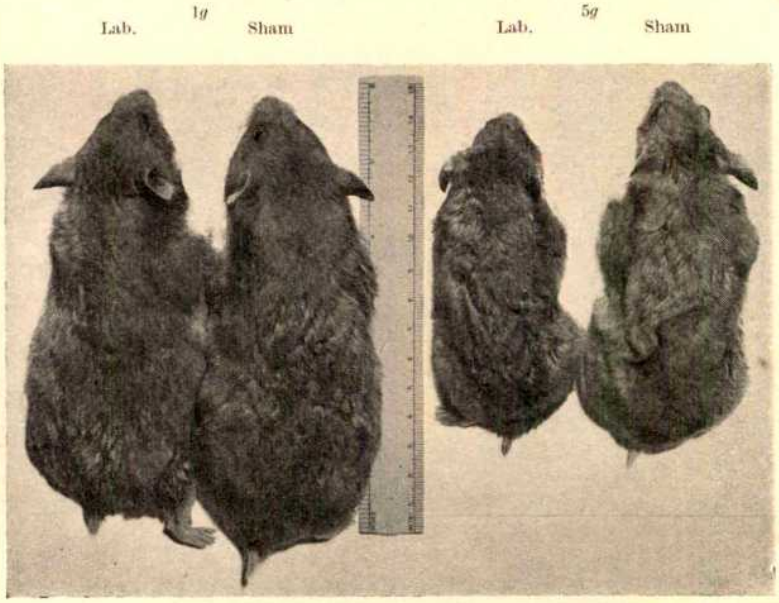

Fig. 3. Typical litter at end of experiment

Table 1. DIFFERENCES IN RESPONSE OF EXPERIMENTAL AND CONTROL ANIMALS
(5 and 6*g*'s combined)

Days of exposure	Difference of differences in change in body-weight* ± *S.E.* (g)	*N* for body-weight	Difference of differences in cumulative intake of 'Laboratory Chow'* ± *S.E.* (g)	*N* for food intake
1	0·5 ± 1·0	9	2·0 ± 1·3	7
2	0·2 ± 1·0	9	3·1 ± 1·6	7
5	−2·3 ± 1·2	9	−1·0 ± 4·6	7
6	−1·9 ± 1·7	8	0·6 ± 6·1	6
11	1·8 ± 2·0	8	0·5 ± 10·6	6
17	−3·1 ± 2·1	8	−6·8 ± 18·7	6
19	−3·5 ± 2·1	7	−4·9 ± 25·1	5

55	−13 ± 5	7	−173 ± 98	5
62	−15 ± 5	5	−256 ± 191	3
82	−17 ± 6	5	−319 ± 247	3

* Difference in differences $= \sum_{i=1}^{i=N}$ [(Labyrinthectomized value in centrifuge − sham-operated value in centrifuge) − (Labyrinthectomized value at 1*g* − sham-operated value at 1*g*)] ÷ *N*, where *i* indicates a given litter. The number *N* is the same as indicated in Figs. 1 and 2, with the exception of data for food intake at 5*g*, where *N* is one less than measured for growth.

known to reduce the threshold for rotatory perception with chronically exposed chickens[6]. Histological observations of inner-ear structures from these hamsters are at present being carried out.

The present results support the previously unsubstantiated contention that developmental changes evoked by chronic centrifugation can be explained primarily in terms of an effectively enhanced gravity. Greater non-rotatory effects are possible with other organisms or with slightly altered centrifugation procedures. Application of labyrinthectomy to related investigations can serve as a useful tool in distinguishing the rotatory from the gravitational effects of centrifugation.

This work was supported in part by grants from the National Institutes of Health.

SURFACE MICRO-STRUCTURE OF SOME VITRAINS OF BRITISH COALS

By F. D. POOLEY, DR. J. PLATT and W. J. HENDERSON
Mining Engineering Department, University of Wales, Cardiff

IT has been known for many years[1] that coal has a porous nature. Laboratory investigations using such methods as adsorption, heat of wetting, and apparent density have all indicated that its ultra-fine structure consists of an extensive system of cavities interconnected by narrow capillaries. Larger micro-cracks can also be present. Such a model explains the ability of coal to act as a molecular sieve, and also accounts for its very large surface area which, it is thought, may be as high as 200 m²/g for some of the lower ranks.

Several workers have put forward theories concerning the ultra-structure of coal substance[2,3]. The work of Bangham *et al.* resulted in a micellular concept based on the existence of highly stable units of coal structure in which the size range of 1000–10 Å was considered to be the most important. It was also suggested that the size of these elemental building units, or micelles, was determined by molecular aggregation processes during coalification and that they would retain some measure of their identity in spite of the inevitable pressures of compaction.

The identification of even the coarser elements of such coal structure is of course beyond the range of even the best optical systems but it is within the range of electron microscopy. Electron micrographs by McCartney and Ergun[4] of thin sections of a vitrain band of a meta-anthracite have revealed platelet-type crystallites in the region of 800 Å in size, together with granular structure as small as 100 Å. These have been shown to be of a graphitic nature and are thought to have been formed and grown from aromatic layer clusters during metamorphic processes.

The preparation of ultra-thin sections of coal by microtomy for viewing in an electron microscope is an extremely difficult process, as indeed it is with most brittle materials. Apart from the dangers of introducing artefacts during cutting, the low degree of contrast of the image can limit the resolution obtained on the micrographs. In addition, the superimposition of the images of particles and pores lying in different planes can complicate interpretation.

An alternative is to use the replica method. Variations of this method have been used for coal and other porous materials to obtain high-contrast images of the undisturbed surface layer of the structure[5,6]. Two-stage techniques are necessary where it is found impracticable to separate carbon replica films directly from the surface which is being investigated. Careful application of the two-stage methods can enable reproducible results to be obtained from the same specimen.

Samples of freshly-fractured surfaces of vitrain bands were selected from a wide range of British coals varying in rank from the 100 group anthracites to the 900 group high volatile bituminous coals of the National Coal Board coal classification system. The vitrinite marceral group was chosen for the samples due to its relative petrological homogeneity and smoothness of fractured surfaces. The samples were crushed below 100 British Sieve Standard in order to present a variety of surfaces, embedded in softened

cellulose acetate, and then coated with a thin film of polyvinyl alcohol which is a water-soluble plastic. The film was then allowed to harden and stripped with the aid of cellulose tape. On most of the coals several films were stripped off to remove loose material before the final replica was made for further processing. In addition to those from the crushed particles, replicas were also taken from small areas of whole vitrain bands for purposes of comparison.

Selected replicas were mounted on glass slides and carbon-coated by vacuum evaporation in the standard manner, following which the plastic substrate was dissolved in successive water baths. This left the carbon replicas floating on the water surface for subsequent collection on electron microscope grids and final metal shadowing at a low angle to improve contrast and accentuate irregularities. It was found that resolutions better than 50 Å could be obtained with this procedure, particularly with fine grain of platinum shadowing. Attempts to interpret structural detail below this limit were not altogether satisfactory due to the masking effects of the deposited metal.

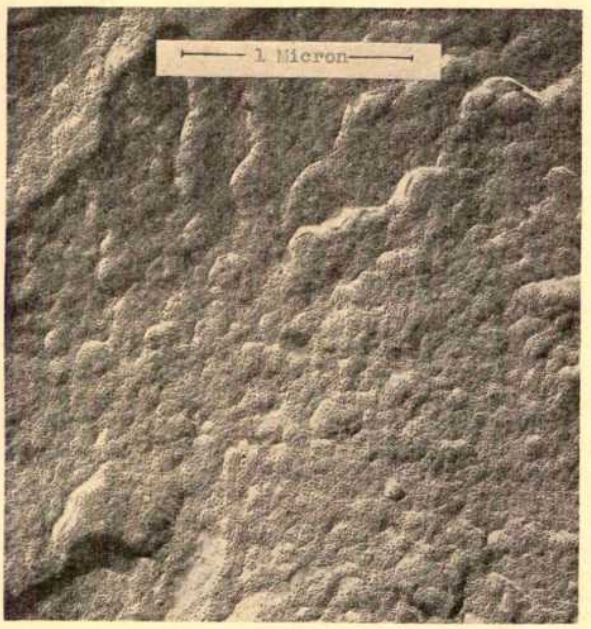

Fig. 1. 900 coa

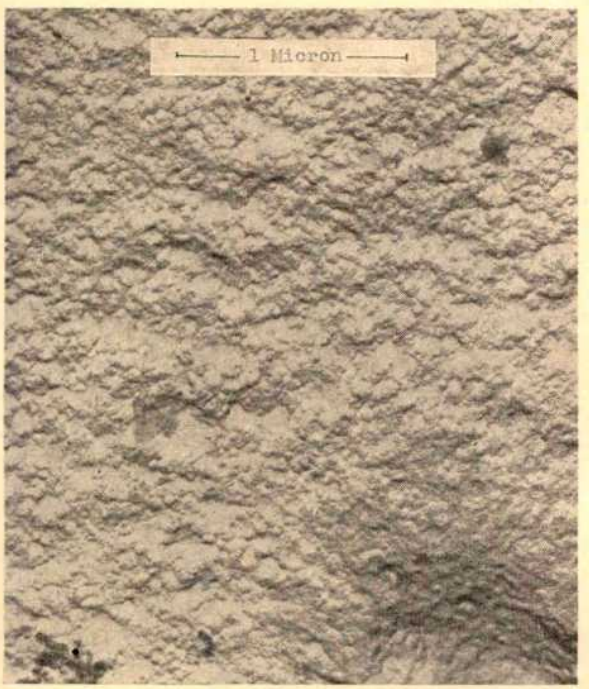

Fig. 2. 700 coal

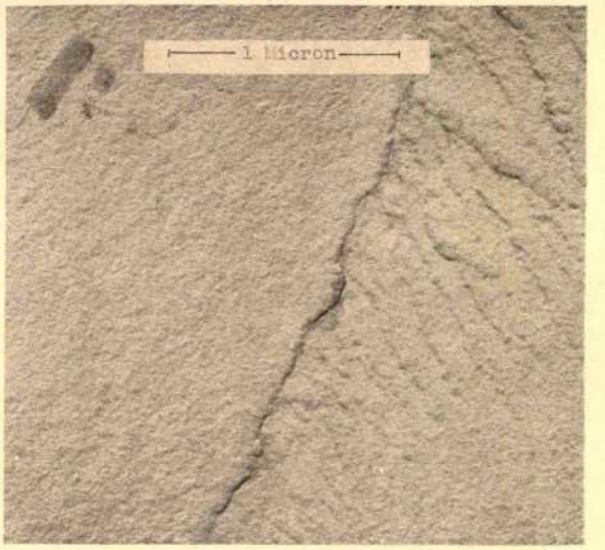

Fig. 3. 400 coal

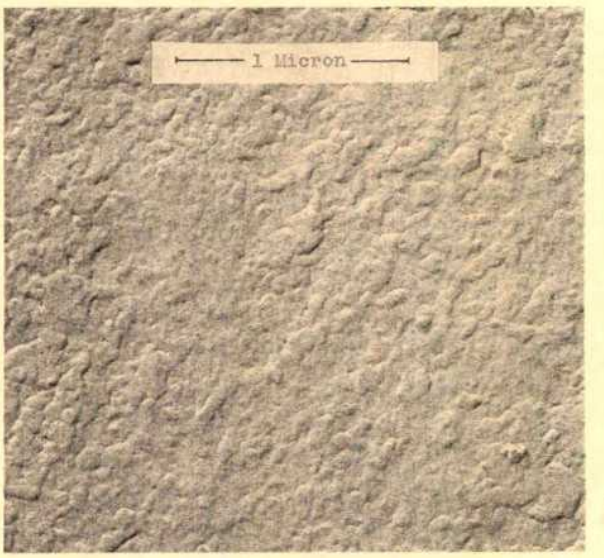

Fig. 4. 100 coal

Electron micrographs were taken of the replicas at a magnification of 10,000 using an A.E.I. *E.M.*6 instrument. Interpretation of results and measurements were assisted by projecting the negatives on to a screen to give magnifications in the region of a quarter of a million times. Photographic enlargements for record purposes were standardized at a magnification of 50,000.

The large number of electron micrographs taken revealed a marked change in surface structure with rank. The lowest rank coals exhibited a relatively coarse granular structure which generally became progressively finer and more compact towards the 400, 300 and 200 groups, increasing thereafter in coarseness in the anthracites. This trend is illustrated in Figs. 1, 2, 3 and 4, each of which is representative of the coal group mentioned. The 900 coal in Fig. 1

was shadowed with gold/palladium; platinum was used for the other three.

The surfaces appear to consist of a series of interconnected generally rounded nodules, or micelles, which give a dimpled effect. Some appear as raised areas and some as depressions. Most appear more flattened than spherical; this feature is shown in the end views along the walls of the depression in the corner of Fig. 2. Several layers are apparent on the fractured surfaces shown, as in many cases only the upper parts of the top layers of units are completely visible. A range of sizes is apparent in each of the illustrations, although close examination of some of the larger units shows them to be agglomerations of smaller ones.

Measurement of the sizes of the most clearly defined micelles for the fourteen coals examined showed them to be in the range of 300–800 Å for anthracites, generally below 200 Å for most of the 200, 300 and 400 groups and increasing to about 500–1000 Å for the lower rank groups.

The trend in micro-structure of coal substances which has been observed is further evidence for the suggested micellular structure of coal and is in keeping with its technical behaviour. The coarser, more open, structure of the lower ranks can account for their known characteristics of high porosity and large internal surface area which, in turn, lead to greater moisture retention and ease of wetting properties. This affinity also makes it much more difficult to upgrade such coals by froth flotation. The larger pore sizes, which go with a coarser structure, also make such coals more susceptible to oxidation and permit the volatile products to be more easily removed on heating so that free-burning is obtained. In addition, low-rank coals generally have high physical strength which again can be related to the relative coarseness of their structure.

Coals in which the finer, more compact structure has been observed are known to be of low porosity, difficult to wet, friable, more easily cleaned by flotation processes, and to have good carbonization properties. Such characteristics are in keeping with reduction in pore diameters. The reversion to coarser structure observed in the anthracites would also seem to be in keeping with their high strengths and other physical characteristics associated with increase in internal surface area. Optical properties of coals have also been found to follow a similar pattern[1].

Application of the electron microscopy replication techniques according to the method described makes it possible to study the micro-structure of coal, with its highly-developed transitional porosity, in much more detail than hitherto. Extension of the work to coal constituents other than vitrain would also seem to be feasible.

RIBONUCLEIC ACID BASE COMPOSITION IN SUBCELLULAR FRACTIONS OF PINE POLLEN (*Pinus ponderosa* LAW)

By PROF. ROBERT G. STANLEY
Forest Physiology Laboratory, University of Florida, Gainesville

AND

ANDREW W. G. YEE
Pacific Southwest Forest and Range Experiment Station, U.S. Forest Service, Berkeley, California

THE mature pine pollen grain contains remnants of two prothallial cells and a functional generative cell imbedded in a tube cell surrounded by a protoplasmic membrane. The pollen exine, with two air-sac-like wings, encloses the intine and protoplasmic membrane. The pollen cell and all its contents are derived from a single haploid pollen mother cell in the sporogenous tissue of the microgametophyte. The male cells derived from the generative nucleus during pollen germination contain the genetic information necessary for expression of the paternal characteristics.

Cytoplasmic organelles are transmitted to the ovule during fertilization along with the male nuclei. These subcellular protoplasmic constituents are incorporated in the developing seed. The potential role of such extranuclear protein or nucleic acid materials on subsequent genetic expressions is still not known[1]. Pollen protein, or ribonucleic acid (RNA), have been suggested as possible sources of the differences in incompatibility reactions which occur when certain pollen tubes penetrate the stylar tissue. Pollen in some cases appears to induce formation of a new protein in the female tissue; the new protein may then inhibit pollen growth[2]. The relationship of such protein to RNA in germinating pollen is assumed to be similar to that reported in other plant cells, that is, microsomal RNA serves as the template for protein synthesis.

Proteins, pigments, and probably RNA are rapidly secreted by pollen on germination[3]. One may assume that the 'incompatible protein' is formed under the influence of a messenger-like RNA diffusing from the pollen[4]; or that it represents a protein recombination diffusing in part from the pollen[5]. Protein or RNA secreted by pollen is derived from the cytoplasm within the pollen. Different proteins, and presumably RNA, are associated with the different subcellular moieties. Since some proteins or RNA do diffuse from the pollen on germination it was thought of interest to compare the composition of the template sources of these chemically reacting components.

This article compares the purine and pyrimidine base compositions of the RNA of the subcellular fractions of pine pollen. This is part of an investigation now in progress on the protein-RNA metabolic activities of germinating pollen.

6-g samples of ungerminated pollen of *Pinus ponderosa* Laws. stored 6–8 months at −15° C were used for each determination. The pollen was homogenized in a solution of 0·5 molar sucrose and 10^{-3} M magnesium chloride. Three sub-samples of 2 g were each homogenized 3 min in a plastic tube with glass beads on a dental shaker ('Wig-L-Bug', Crescent Mfg. Co., Chicago). This resulted in about 98 per cent grain breakage. All homogenizing and fractionating were done at 0° C. The homogenates

were transferred to 50-ml. plastic centrifuge tubes and centrifuged 15 min at 1,000*g* to separate large cell fragments, that is, wall, starch granules and nuclei. The precipitated cell fragments were resuspended in about 15 ml. sucrose–magnesium solution and recentrifuged. The combined supernatants (S_1) were centrifuged at 14,000*g* for 30 min to precipitate the mitochondria. The mitochondrial pellets were resuspended in 10 ml. sucrose–magnesium solution and recentrifuged. The supernatant from the mitochondrial fraction (S_2) were centrifuged at 100,000*g* for 90 min in a Spinco refrigerated preparatory centrifuge to sediment the microsomes. The microsomal particles prepared in this manner were checked for sedimentation characteristics in a Spinco analytical centrifuge and were found to consist primarily of particles sedimenting with a normal plant microsomal constant of 73 *S*. The supernatant (S_3) remaining after removal of microsomes was used for soluble-RNA analyses.

The sedimented fractions were mixed with 0·5 M trichloroacetic acid (TCA). An equal volume of solution of 1·0 M TCA was added to each supernatant fraction. The precipitates were allowed to stand overnight at 0° C and then centrifuged. The TCA supernatants were discarded and the insoluble precipitates washed in the following sequence of 5 ml. volumes of solution: twice in 2 per cent perchloric acid; three times in ethanol–ether–chloroform (2 : 2 : 1) for 15 min each at 25° C; once in 70 per cent ethanol and twice in 2 per cent perchloric acid. Except for ethanol–ether–chloroform, the washing was for approximately 5 min at 4° C. The washed precipitate was then extracted over a 12-h period at 4° C with constant slow shaking in five changes of 1·0 N perchloric acid. The perchloric acid extracts were combined and neutralized with N potassium hydroxide and the potassium perchlorate precipitate removed. The neutralized perchloric acid extracts were then concentrated by low-temperature vacuum (about 35° C) and an equal volume of 2·0 N hydrochloric acid was added; the extract was hydrolysed in a sealed tube for 1 h at 100° C. This hydrolysate was directly streaked under a stream of cold air on to Whatman No. 1 filter paper previously washed with 0·1 N hydrochloric acid and chromatographed for 18 h ascending in isopropanol–hydrochloric acid–water (68 : 17·6 : 14·4) at room temperature. Individual bands were identified under ultra-violet light, cut from the paper and eluted with 0·1 N hydrochloric acid to a constant volume of 25 ml. The absorbance of the eluate was measured with a Cary Model 11 recording spectrophotometer from 220 to 290 mμ. Yeast RNA (commercial grade, California Foundation for Biochemical Research) was used as comparison control in all extraction and hydrolytic steps; purines and pyrimidines (C_fP spectral grade, Calif. Foundation for Biochem. Res.) were used for chromatographic and ultra-violet standards.

Determinations were made in 1959, 1961 and 1964 on pollen of the same species from trees in the same locality. Efforts were made in the 1959 and 1961 analyses to compare the ultra-violet data with phosphorus and orcinol assays for total RNA and base component fractions. Results from the three methods often varied by 10 per cent. Ingle[6] showed that correlation between the three methods is generally difficult and should not be expected. Ingle[6] and Young[7] concluded that the ultra-violet values are the most reproducible and reliable. Only the ultra-violet values are used in this article. The means of three separate replicate experiments were compared. The RNA hydrolysate absorption data for all years were in good agreement. Table 1 lists the results of these experiments in terms of the mole percentage ratios of the nucleotide base components in the different subcellular RNA fractions of *Pinus ponderosa* pollen. Related values reported by other workers and control yeast determinations are included. Hydrolysis of RNA in hydrochloric acid causes a breakdown of about 5 per cent of cytosine and uridylic acid[8]. This was corrected in calculating the mole percentage values. The chromatograms were carefully scanned and eluted in search for other purines and pyrimidines which have occasionally been reported in bacteria and plant RNA hydrolysates. No other purines or pyrimidines were found.

From the results recorded in Table 1, conclusions can be drawn regarding the nature of RNA present in pollen and the significance of previous reports of nucleotide base ratios of whole plant or organ extracts. For example, values for the nucleotide components of pine pollen RNA reported by Vanyushin *et al.*[11] represent an average of the extractable RNA in all combined pollen cellular components. However, a comparison of the base composition of the RNA in the fractionated pollen cell components affords a different and more illuminating picture. The data in Tables 1 and 2 suggest that plant tissues which have high cell wall residues, such as tobacco leaf or cotton cotyledons, or the first centrifuge fraction from pollen homogenates, have a high ratio of guanine (Table 1) compared with uracil (Table 2), the usual base nucleotide with which guanine pairs.

If RNA is correctly described as a tetranucleotide with helical regions, then the molar proportions of purine nucleotides should approximate the molar proportions of pyrimidine nucleotides. Values of these proportions determined for pine pollen microsomes and yeast RNA (Table 1) agree with this concept. The values close to unity for guanidine/cytosine and adenosine/uridine ratios in pine pollen microsomes (Table 2) further indicate that the RNA of the ribosomal particles conforms to the general theory. Considerable variation from unity can be expected and was found in the soluble-RNA nucleotide fraction. The supernatant probably contains polynucleotide messenger-RNA components or hydrolysed RNA moieties. However, large deviations were also found in the purine/pyrimidine ratios of the mitochondrial fraction, and the cell wall fraction of ungerminated pine pollen. The fact

that our results for the pollen microsomal and yeast RNA composition (Table 1) compare well with the values in the literature suggests that these data are correct. Since the present base-paired double strand concept of RNA does not account for all the observed purine/pyrimidine ratios of pine pollen fractions, some alternative explanation is required.

In RNA the helical regions are generally considered to comprise about 50 per cent of the structure of nucleotides[12]. A disproportionate presence of one base in an RNA strand would modify the helical regions and RNA compactness. Subcellular fractions of peas, spinach, and other plant leaves have purine/pyrimidine ratios between 1·20 and 1·29 (ref. 13). The base ratios found in the RNA of supernatant and mitochondria fractions of pine pollen are similar. These modest differences from 1·0 in base ratio could be reflected in variations in the compactness of the helical RNA strands of the mitochondria and soluble-RNA components[14].

The relatively high values of the purine/pyrimidine ratio in the pine pollen cell wall fraction is probably caused by the presence of nucleotide components bound in, or on, the pollen walls. Coenzyme components of guanosine and adenosine are essential to pollen growth[15], and are presumably present in pollen. Such mononucleotides may be tightly bound in protein-cell wall complexes in ungerminated pollen. These bound nucleotides may be released with germination or ageing; or they may be released with extended acid extraction such as is used to release particulate bound RNA. The extractability and form of pine pollen protein diffusate changes substantially during storage[16]. This suggests that many enzyme–coenzyme moieties are bound, or soluble to different degrees in the mature pollen grain, and may account for the distorted base ratio values in the cell wall fraction.

The difficulties apparent in the interpretation of nucleotide base ratios of RNA from plant cellular fractions are compounded in the case of RNA of whole plant tissues. Heyes[17] has shown that the base ratio of RNA from root cells differs in cells of different ages. The soluble and particulate RNase also changes as plant cells age[18]. Thus, nucleotide base ratios of plant cells may not indicate changes in the type of RNA the plant is synthesizing, but rather changes in the concentration of a particular cell moiety: for example, it brings about more microsomes or mitochondria, or changes in the RNase activity of the cells.

Our results indicate that efforts to interpret studies of the base ratios of RNA extracted from whole organs requires greater caution and understanding of the sources of the RNA than has generally been the practice. Attempts to establish phylogenetic relationships using base composition of RNA extracted from whole organs has not met with success[10,13]. Base composition of DNA, primarily limited to cell nuclei, does provide a basis for phylogenetic comparison. A more valid comparison of base composition of RNA in different species may result when only the base components of RNA from a stable subcellular particle are compared. However, the ubiquitous nature of many enzymes in various plant cells suggests that the controlling-RNA involved in their synthesis may be very similar. Differences in RNA expression may be related to functional mechanisms rather than mere composition. Definitive knowledge of this subcellular characteristic would indeed be valuable for further studies of growth and differentiation.

We thank Dr. Paul O. P. Ts'o for the determination of the sedimentation constant of the microsomal fraction which we isolated from pine pollen. This study was initiated while the authors were visiting research workers at the Biological Laboratories, California Institute of Technology.

LONG-TERM CULTURE OF EMBRYONIC CELLS OF *Drosophila melanogaster*

By DR. MASAKATSU HORIKAWA, MISS LEE-NIEN LING and PROF. ALLEN S. FOX
Department of Genetics, University of Wisconsin, Madison

IMPROVED methods for culturing insect tissues, particularly those of *Drosophila melanogaster*, are continually being sought due to the importance of such material for studies in genetics, molecular biology, virology and developmental biology. In a previous paper we reported the successful growth *in vitro* of embryonic cells isolated from eggs of *Drosophila melanogaster*[1]. This article describes the properties of cells which have been maintained in long-term culture. At the time of preparing this report seven separate cell lines have been maintained for periods ranging from 80 to 520 days. The latter, line *A*, is described in detail; the other lines exhibit characteristics which are essentially similar.

The techniques used for the establishment of primary cultures, the medium used (*H*-5), and the methods for determining cell number and chromosome counts have been described in the earlier paper. The initial cell suspensions were obtained from eggs collected over a 6-h period from inseminated females of the Oregon *R-EL2* stock. The cultures are grown (without shaking) at 30° C in *T*-30 flasks containing 5 ml. of medium, and are transferred every 10 days. Most of the cells in such cultures freely float in the medium, but some are attached to the glass. At the time of transfer the latter are scraped free, all the cells are randomly suspended by gentle pipetting, transferred to a tube, and centrifuged at 2,500 r.p.m.

for 5 min. The old medium is then decanted and the cells resuspended in about 1 ml. of fresh medium. If the cell count is high enough the suspension is divided into two portions, each is made up to 5 ml. by addition of medium and is transferred to a *T*-30 flask; otherwise the suspension is brought to 5 ml. and is transferred without division.

After four transfers of line *A*, crystal formation in the medium became a serious problem. The fifth transfer was made into an altered medium, *H*-6 (Table 1), and this new medium has been used in all subsequent transfers. The other lines were established by growth of the primary cultures in *H*-5 but the first and subsequent transfers were made into *H*-6. Growth rates were the same in *H*-5 and *H*-6, but crystals were not formed in the latter. Both media were supplemented with 10 per cent calf serum.

As shown in the previous paper, there are two distinctive cell types in the initial cell suspensions, small (5–10μ in diameter) and large (20–35μ). The large cells average only one division during the initial period of cultivation while the small cells enter logarithmic multiplication with a mean generation time of 25–30 h, reaching maximum number in 4–5 days, at which time they had multiplied in number almost five times.

The proportion of large cells has gradually decreased during repeated transfer. After 50 days of cultivation (five transfers) they constituted 20 per cent of the cell population, in contrast to 47 per cent in the initial suspension, and they barely maintained their number during the fifth growth period (Fig. 1*a*). After 160 days (sixteen transfers) they had decreased to 14 per cent of the population (Fig. 1*b*), and at 430 days they constituted only 4–7 per cent of the population (Fig. 1*c*). Mitotic figures are not difficult to find in the large cells of primary cultures (Fig. 2*a*), but they are only rarely observed in later transfers.

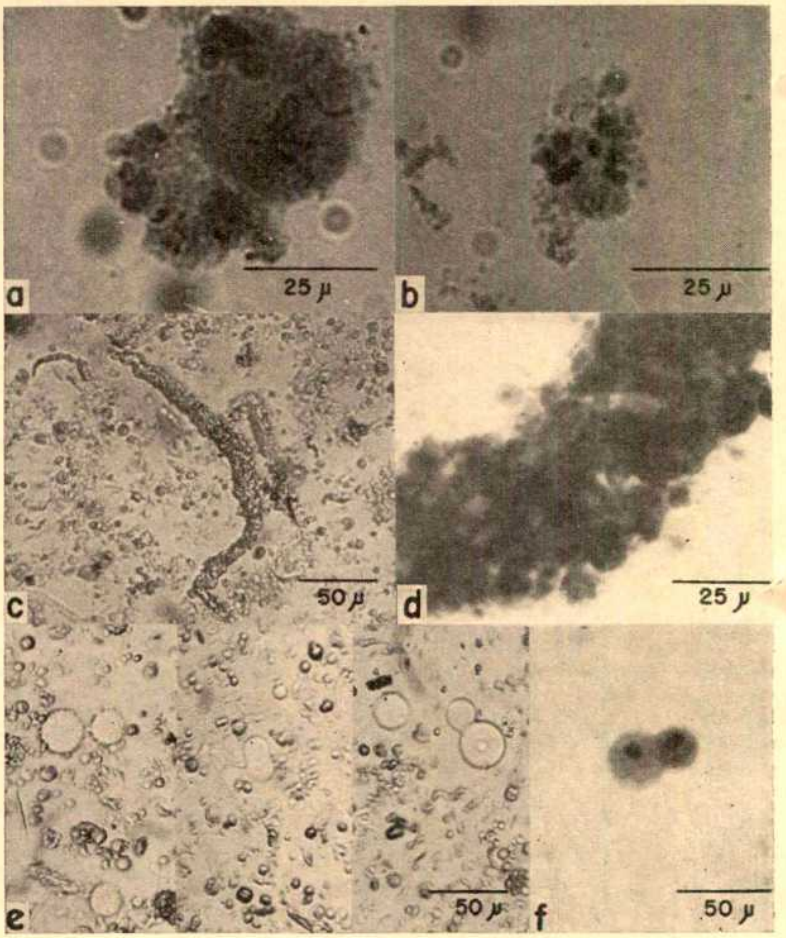

Fig. 2. Photographs of cultivated cells taken by light microscopy. *a* and *b* are cells squashed in water, stained with 1 per cent aceto-orcein; *d* is squashed in culture medium, stained with Giemsa dye; *f* is stained with Giemsa; *c* and *e* are living, unstained cells. *a*, Mitotic figure in large cell; *b*, mitotic figure in small cell; *c*, tubule-like and string-like non-random aggregates of small cells; *d*, similar aggregate showing cell nuclei; *e*, large, clear cells which first appear after 160 days of cultivation (sixteen transfers); *f*, budding large cell, showing nucleus in original cell and in bud

Small cells enter logarithmic multiplication immediately after each transfer, although their growth rate has declined with subsequent transfers. After five transfers their mean generation time was 32 h (Fig. 1*a*), while after sixteen transfers it was 48 h (Fig. 1*b*). At 430 days the mean generation time had increased to 69 h (Fig. 1*c*), but the line was still maintaining itself. The other lines have exhibited similar deceases in growth rate, and none, as yet, has undergone adaptation. Mitotic figures are readily observed in small cells both in primary cultures and in later transfers (Fig. 2*b*).

Chromosome counts are readily made in large cells but are difficult in small cells because of their size and the extreme condensation of the chromosomes. Nevertheless, we have previously shown that chromosome number remains constant at the diploid number 8 in primary cultures. The distribution of chromosome numbers after 50 days of growth did not differ significantly from that at 10 days, but some evidence of haploidy, hypoploidy and hyperploidy was evident after 160 days (Fig. 3). The modal chromosome number, however, was still diploid.

Large cells rapidly formed grape-like aggregates in primary cultures, so that the proportion of unaggregated cells of this type is small at the end of the first growth period. Small cells begin to form aggregates only after the first transfer, and continue to do so in subsequent transfers. Some of these are grape-like clusters, apparently resulting from random clumping, but others exhibit non-random structure (Fig. 2*c*). These look like tubules or strings of cells, and nuclei are apparent in many of the cells when they are squashed and stained (Fig. 2*d*). The

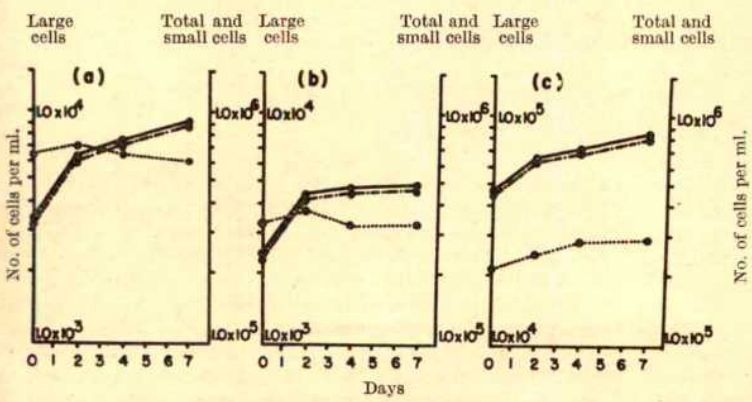

Fig. 1. Growth curves of embryonic cells *in vitro*. *a*, After 50 days of cultivation (five transfers); *b*, after 160 days of cultivation (sixteen transfers); *c*, after 430 days of cultivation (forty-three transfers). Medium H-6 supplemented with 10 per cent calf serum. Temperature, 30° C. ———, Total cells; —·—·—, small cells; · · · · · · , large cells

characteristics and consequences of aggregation are being studied.

A new cell-type, which appeared in line *A* after sixteen transfers (Fig. 2*e*), has also appeared in the other lines, and has continued to persist in all. These are large (15–30μ in diameter) and clear, and are distinct from the original large cells which possess granulated cytoplasm. Some of these cells divide unequally, giving rise to buds which may become detached from the parent cell and gradually increase in size. In favourable cases chromosomes can be seen both in the parent cell and the bud during division, and a nucleus is present in both after the completion of mitosis (Fig. 2*f*). These cells resemble embryonic neuroblasts[2] in size, appearance, and mode of division. Other cells of the same apparent type undergo equal division.

Table 1. COMPOSITION OF MEDIUM *H*-6

Constituents	Amount (mg/1,000 ml.)	Constituents	Amount (mg/1,000 ml.)
Salts		Amino-acids	
$NaH_2PO_4 \cdot 2H_2O$	200	Lactalbumin hydrolysate	7,500
$NaHCO_3$	350	L-tryptophan	80
KCl	200	L-cysteine hydrochloride	20
$CaCl_2 \cdot 2H_2O$	20		
$MgCl_2 \cdot 6H_2O$	100	Vitamins and nucleotides	
NaCl	7,000		
		Yeast extract	1,200
Sugars			
Glucose	5,500	*p*H indicator	
Sucrose	5,500	Phenol red	10
Antibiotics			
Penicillin *G* (sodium salt)	30	*p*H, 6·5. Sterilization by	
Streptomycin sulphate	100	passage through a Seitz filter	

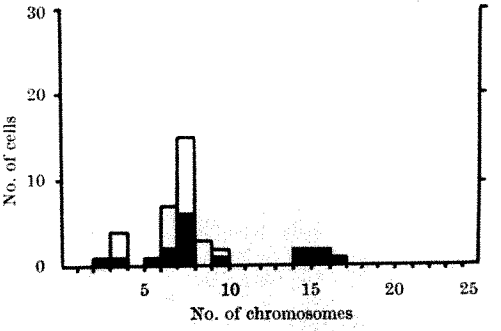

Fig. 3. Distribution of chromosome numbers in line *A* after 160 days of cultivation (sixteen transfers). ■, Large cells; □, small cells

In summary, most of the cells in long-term cultures retain their embryonic appearance, normal chromosome number, and their ability to divide. Some evidence of abnormal chromosome numbers is found, however, and the formation of non-random aggregates and of a new cell type suggests limited differentiation.

This work was supported by research grants from the National Institutes of Health and from the Wisconsin Alumni Research Foundation. One of us (M. H.) is on leave from the Department of Experimental Radiology, Faculty of Medicine, Kyoto University, Japan.

COTYLEDONARY STIPULES IN THE MYRTACEAE

By STELLA G. M. CARR and PROF. D. J. CARR
Queen's University, Belfast, Northern Ireland

THE presence or absence of stipules is one of the most consistent of the vegetative characters used by angiosperm taxonomists and has considerable importance in both classification and identification of flowering plants. Unfortunately, much of the information in the standard works in English is either incorrect or incomplete. For example, it is generally but erroneously believed (see, for example, ref. 1) that the members of the order Myrtales lack stipules. Weberling[2] has shown that they occur in most families of this large order. They are present on the adult leaves of 44 out of the 46 genera of Myrtaceae which he examined. He did not find stipules in *Eucalyptus* L'Hér. or *Angophora* Cav. It is true that he examined only a few species of *Eucalyptus*, but a more extensive investigation confirms his conclusion. We find that stipules are absent also from the juvenile foliage of both *Eucalyptus* and *Angophora*. However, in *Angophora* and in many species of *Eucalyptus* (as well as in many of the other genera of Myrtaceae investigated by Weberling) the cotyledons bear stipules. In the eucalypts and in *Angophora* the stipules occur on or near the margins of the petioles, two to six per cotyledon. In other genera (*Leptospermum*, *Melaleuca*, *Tristania* (Fig. 1*a*), *Syncarpia* (Fig. 1*b*), *Agonis*, *Callistemon*, *Calythrix*) there are usually six or more, forming a transverse row across the base of the petiole, as described[2] for the adult leaves of Combretaceae. In most cases, the cotyledonary stipules are differentiated into a stalk and an apical part which consists of small densely staining cells, which are apparently secretory. Although the nature of the secretion has not been adequately investigated, it is certainly not oil. The stipules are quite distinct from the emergent oil-glands which are characteristic of certain eucalypts and of *Angophora*. The occurrence in them of vascular elements in at least one species (*Eucalyptus ferruginea* Schau.) suggests that the structures, which we concur with Weberling in identifying as stipules, are not mere enations. It is fair to warn taxonomists, however, that their usual examination with a magnification of ten times or less may be inadequate to reveal the stipules.

In the aforementioned genera, other than *Eucalyptus* and *Angophora*, the cotyledonary stipules resemble those of the adult leaves. In *Angophora* each cotyledon has two three-lobed stipules; occasionally a small free lobe is associated with a two-lobed structure. Similar stipules, sometimes three-lobed, but in many cases simple (Fig. 1*c* and *d*), are present also in certain species of *Eucalyptus* L'Hér. It is convenient[3] to divide this genus into two genera, *Eucalyptus* L'Hér. emend. Carr and Carr and *Symphyomyrtus* Schau. emend. Carr and Carr. The division is based principally on the characters of the flower, inflorescence and seed, but also depends on vegetative characters. In *Eucalyptus sensu stricto* the series Eudesmieae[4] (a group which exhibits many apparently primitive characters) consists of species all of which have well-developed stipules, with the exception of *E. ebbanoensis*, *E. gamophylla* and *E. odontocarpa*. The two latter are either very closely related or conspecific[5]. These species have structures which, by analogy, can be described as stipule rudiments. Stipules also occur in series Miniatae and in most species of sections Renantheroideae and Renantherae. In *Symphyomyrtus*, on the other hand, they are lacking in most species but are especially prominent in those of the series Corymbosae

(Maiden) S. T. Blake. In the series Transverse they are well developed in some species and occasionally present in others. They are also to be found on a small percentage of seedlings of some species of series Dumosae and Leptopodae. The presence of cotyledonary stipules in *Angophora* and in the eucalypts means that all the genera of the Myrtaceae which have been examined include species which are stipulate in at least some stage of their ontogeny. It is of interest that in some genera stipules are formed only at the cotyledonary stage and that in some species of these genera they are either inconstant or completely lacking. In certain eucalypts (for example, *E. stellulata*) only about 10 per cent of the seedlings have stipules and often only one stipule appears on one of the cotyledons. Stipulate genera of a number of other families have been examined for the presence of cotyledonary stipules. They are lacking in Violaceae, Rosaceae, Salicaceae and Fabaceae. In *Viola* and in members of Rosaceae and Fabaceae the first seedling leaves are stipulate, but those of *Salix* and *Populus* are exstipulate. Other families include both stipulate and exstipulate genera. In *Clarkia* and *Godetia* (Onagraceae tribe Onagreae), which Weberling records as entirely exstipulate, there are no cotyledonary stipules, but in *Hedera* (Araliaceae), which has exstipulate leaves, the cotyledons are stipulate; in *Tropaeolum minus* and *T. speciosum* (Tropaeolaceae) all the leaves are stipulate, whereas in *T. majus* only the primary leaves[6] have stipules.

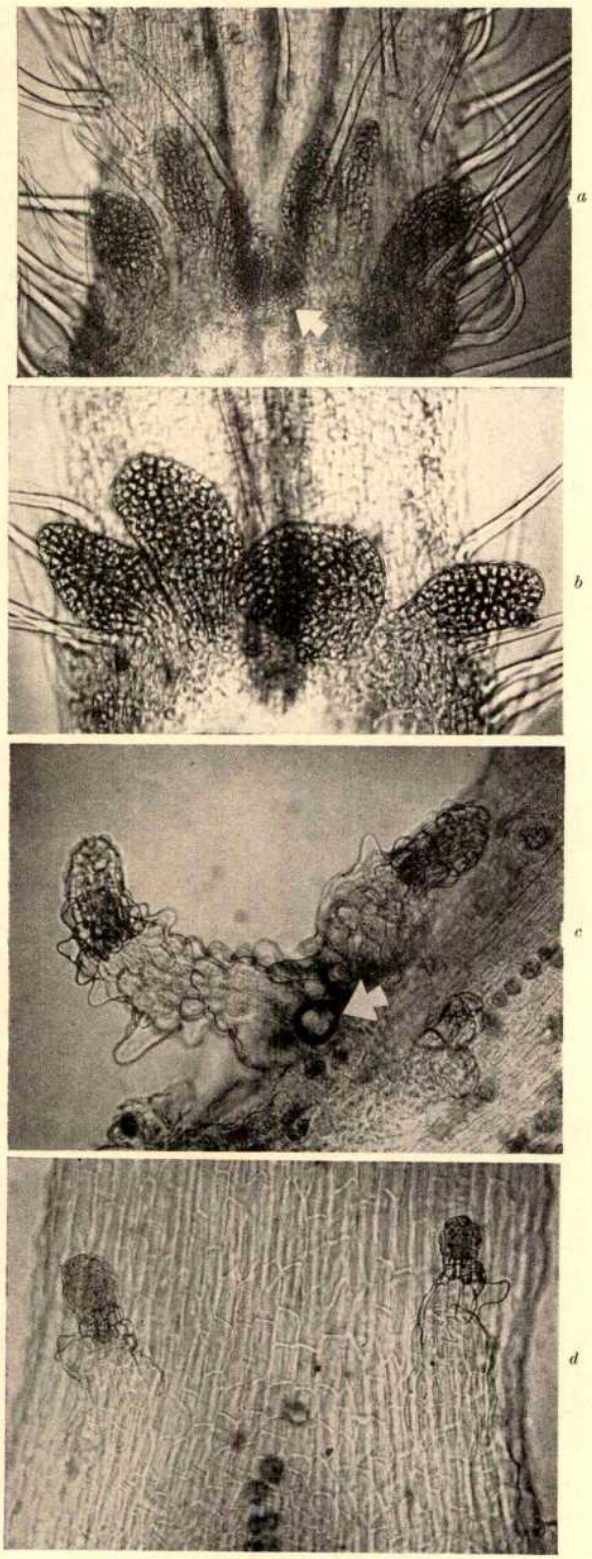

Fig. 1. Cotyledonary stipules of members of Myrtaceae. *a*, *Syncarpia glomulifera*. Arrow indicates axillary bud of cotyledon (× *c.* 68); *b*, *Tristania conferta* (× *c.* 103); *c*, *Eucalyptus tetragona*. Arrow indicates oil gland at base of stipules (× *c.* 78); *d*, *Eucalyptus rossii* (× *c.* 83)

With regard to the presence or absence of stipules one may therefore classify the flowering plants into four groups, as shown below:

Group	Cotyledons	Seedling leaves	Later leaves
1	−	±	−
2	+	+	+
3	+	±	−
4	−	±	+

+ Indicates presence of stipules.
± Indicates stipules present in some species, absent in others.

Certain genera, usually described as 'exstipulate', include species belonging to groups 1 and 3. In such a genus, the completely exstipulate condition (group 1) may have arisen by suppression of the production of stipules at successively lower nodes of the primary shoot, resulting ultimately in complete loss of ability to produce them even on the cotyledons. In the eucalypts, these observations are relevant to the evolutionary trends, evidence for which we have published elsewhere[3,5,7], many of which involve suppression of morphological structures. In *Eucalyptus* s.s., for example, there is a tendency towards suppression of the sepals. Large persistent sepals are present in some members of Eudesmieae, but sepals are completely absent from members of Renantherae; for example, *E. stellulata*. This trend parallels similar trends in other characters of the flower (for example, grouping of stamens, divergence of anther lobes) and vegetative characters (for example, stellate hairs, lignotubers). There are parallel trends in the occurrence, number, size and morphology of the cotyledonary stipules in this genus. We have described[5] the remarkable convergence of the sister genus, *Symphyomyrtus*, in which similar evolutionary trends can be distinguished. The suppression of stipules has apparently been one of the features of evolutionary change in *Symphyomyrtus*, since they are well developed in those of its series which possess larger constellations of ancestral features and are absent from species which on many grounds could be considered advanced.

We thank Mr. T. R. N. Lothian, director, Adelaide Botanic Garden, for seed of many genera, and Mrs. F. L. Ross, Waroona, Western Australia, for specimens.

LETTERS TO THE EDITOR

ASTRONOMY

Atomic Standards of Frequency and the Second of Ephemeris Time

On the authorization of the twelfth General Conference, the International Committee of Weights and Measures assigned, in October 1964 (ref. 1), the frequency 9 192 631 770 hertz to the well-known transition of caesium-133 at zero field, for temporary use pending consideration of a new definition of the second; the second, as at present defined, is the second of ephemeris time. The number 9 192 631 770 with a quoted probable error of ±20 is that originally determined by Markowitz *et al.*[2] by the comparison, during the period 1954·0 to 1958·5, of an integrated measure of atomic time based on the frequency of the caesium transition with the measure of ephemeris time (E.T.) as determined by observations of the Moon with moon-cameras. Subsequent comparisons over longer periods have tended to confirm that this frequency lies within the uncertainty quoted.

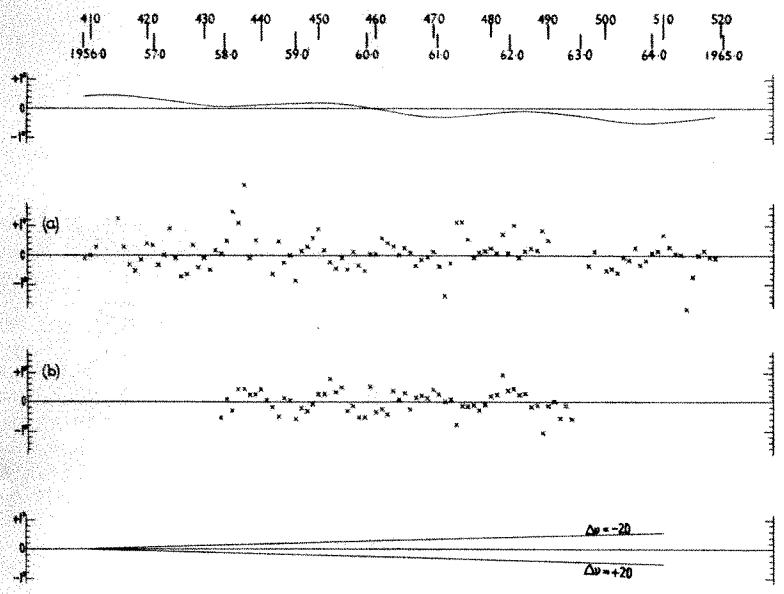

Fig. 1

However, the International Astronomical Union at its General Assembly in August 1964 recommended the use of a new IAU System of Astronomical Constants[3]; its adoption leads to modifications of a periodic nature in the lunar ephemeris which affect the determination of ephemeris time from observations of the Moon. Moreover, Eckert[4], in the course of a comprehensive recalculation of the main problem of the lunar theory, discovered a numerical error in the coefficient of one of the periodic terms of Brown's theory; the presence of this error in the lunar ephemeris has since been confirmed by analysis of both the meridian[5] and occultation (unpublished) observations.

The application of these two periodic corrections to the lunar ephemeris affects the determination of the deduced frequency in terms of the (ephemeris) second by amounts that could, over short intervals, reach as much as 40 (or even 50) hertz. The correction to the deduced frequency depends on the precise method of discussion and, for this reason, no estimates are given in respect of previous determinations. However, two new determinations, incorporating these corrections, have recently been made; the purpose of this communication is to report that they confirm that the frequency of the caesium transition is close (within its previously quoted probable error) to the adopted value of 9 192 631 770 hertz. It is emphasized that, as in all other current determinations, the measure of the (ephemeris) second is deduced from observations of the motion of the Moon around the Earth, although it is defined in terms of the motion of the Earth around the Sun.

The new determinations are based on the provisional discussion of two homogeneous series of lunation mean values of ΔT = E.T. − U.T.2 deduced from: (*a*) the Washington meridian observations[6] of the Moon from 1956·0 to 1965·0; (*b*) the observations of occultations of stars by the Moon as collected and reduced at Herstmonceux (to be published), from 1958·0 to 1963·0.

In both series the observations have been corrected for the irregularities of the limb of the Moon. The values of ΔT, amended for the effect of the corrections above, are compared with the corresponding lunation mean values of ΔA = A.T. − U.T.2, where A.T. is an atomic time scale based on the adopted frequency of 9 192 631 770 hertz, thus eliminating U.T.2. In this preliminary discussion straight lines are fitted to the differences $\Delta T - \Delta A$; the slope of the lines indicates directly the correction to the frequency (+0ˢ·01/lunation = − 36 hertz). The formal results are:

(*a*) Meridian, 1956·0–1965·0: −14 ± 5 (standard error).

(*b*) Occultations, 1958·0–1963·0: +2 ±11 (standard error).

The residuals, in seconds of time, from these fitted straight lines are plotted in Fig. 1 in which the abscissa is the lunation number. For comparison there are also given: in the upper diagram, as a continuous line, the effect on ΔT of the corrections to the lunar ephemeris; in the lower diagram, the slopes corresponding to frequency corrections of ±20 hertz.

There is some evidence, especially in the occultation values (*b*), of the presence of periodic terms; these are probably due to the effects of selection, which is inevitable in both forms of observation, on the difference between the centre of mass and the centre of figure of the Moon. The consequence is to enhance the importance of the observations at the ends of the series; for example, the omission of the last six lunations from the occultation data changes the deduced correction from +2 to −19. Pending a more elaborate discussion, all that can be said with reasonable certainty is that the frequency of the caesium transition is unlikely to lie outside the range 9 192 631 750–775 hertz. Formal estimates of error have little significance.

On the Possible Origin of the Lunar Maria

RECENT close-up photographs of the lunar surface on the western shores of Oceanus Procellarum, televized back to Earth by the Russian soft-lander *Luna* 9 on February 4, revealed for the first time the detailed micro-structure of typical mare ground down to a cm–mm scale. While the conspicuous surface roughness manifest on this scale could have been anticipated from previous radar-echo work[1], and while most—if not all—of it may be due to micro-meteoritic etching, this new evidence of severely local nature gives rise to wider issues concerning the origin of lunar maria which have so far not been mentioned in this connexion.

As is well known, the origin of such formations has so far been sought in terms of planetesimal[2] or cometary[3] impacts, as well as of volcanic phenomena[4], with so far indecisive outcome. The aim of this communication is, however, to emphasize in this connexion another prominent and large-scale characteristic of the lunar maria which has so far not been properly faced and which—when properly understood—must bear vitally on the problem of their origin: and that is a conspicuous disparity in their distribution on the two hemispheres of the lunar globe.

Ever since the first Russian photographs of the far side of the Moon, taken by *Lunik* 3 on October 7, 1959 (and supplemented since by improved work by *Zond* 6 on July 20, 1965, of much higher resolution), became available, it has been evident that all lunar maria are very largely situated on one hemisphere facing the Earth; and with a slight rotation of the principal axes of inertia of the lunar globe this disparity could be made almost complete.

What could be the cause of this striking phenomenon? A gravitational shielding of the Moon from external impacts by the Earth having proved to be utterly ineffective[5], another type of the Earth–Moon interaction must be sought to provide the desired clue; and I should point out a possible relevance, to our problem, of certain facts which follow from retrograde extrapolation of the tidal evolution of the Earth–Moon system in the past. According to a recent fundamental work by Gerstenkorn[6], confirmed since by more extensive computations by MacDonald[7], a linear extrapolation of the present rate of tidal friction in the Earth–Moon system backwards in time shows that, about 1,800 million years ago, the Moon's centre approached that of the Earth at a distance of 2·89 Earth radii according to Gerstenkorn, and 2·72 such radii according to MacDonald—yielding a mean of 2·8 ± 0·1 Earth radii or 17,800 ± 600 km. Moreover, the angular momentum of axial rotation of the lunar globe is relatively so small that synchronism between the Moon's rotation and revolution was enforced at all stages.

It was Gerstenkorn who first pointed out that the foregoing distance of minimum approach is virtually identical with the terrestrial Roche limit of a gravitational danger zone, within which any self-gravitating body is bound to suffer mechanical damage—and eventually be torn apart—by tidal action of the Earth, regardless of whether it is fluid or solid[8].

Now—and this may be significant in our connexion—according to both Gerstenkorn and MacDonald, the Moon's dip in the terrestrial Roche limit did not engulf the entire lunar globe, but only the 'front' hemisphere facing the Earth. The mechanical damage which the lunar surface may have suffered in the hands of the Earth during their brief close embrace, and its bearing on possible origin of lunar craters, has already been considered by Alfvén[9]. Now the distribution of craters over the entire surface of the Moon appears to be reasonably uniform—if anything, they cluster on the far side. What does not seem to have previously been noted is, however, the fact that a conspicuous asymmetry in the distribution of the maria over the lunar globe appears to be consistent with an assumption that the mare plains may constitute 'scars' of mechanical damage, wrought on the lunar hemisphere which entered the Roche limit by disruptive tides of the Earth.

At the first sight, such a hypothesis would seem to require that the maria be 'lowlands' lying below the level of the continental areas, which is not found to be generally the case[10]. However, the possibility cannot be ruled out that the strain to which the lunar crust may then have been exposed could have led to its cracking, and that lava was exuded to the surface to fill up the original scars.

Could, however, an adequate reservoir of molten lava have been available in sub-surface layers, and if so, what could have been the source of heat to melt it? It could scarcely have been radiogenic heat; for no radioactive elements of sufficient cosmic abundance are known with the requisite half-lives close to 2,000 million years.

However, one gravitational process by which this could have been accomplished at the time would be through viscous dissipation of the bodily tides raised in the mass of the Moon by terrestrial attraction which, at the time of the Moon's closest approach to the Earth, should have been about 10^4 times greater than at the present time. The amount of internal heat which can be so generated[11] is at present minute, but 1,800 million years ago it could have been a different story; and it is possible that the lava-filled lunar maria represent visible reminders of that time.

RADIOPHYSICS

Observations of Circularly Polarized OH Emission and Narrow Spectral Features

IN a recent publication we reported the detection of linearly polarized OH emission from a localized region near the radio source *W*3 (ref. 1). Although the mechanism of production of the polarized emission was not understood, we pointed out that, among several possible mechanisms, the Zeeman effect was unique because it alone would give rise to circularly polarized radiation. This communication reports observations made with a circularly polarized feed horn on the 140 ft. radio telescope of the National Radio Astronomy Observatory, Green Bank, West Virginia, between November 11 and 12, 1965. The receiver used was an autocorrelation-type radiometer with 100 channels[2]. Bandwidths of 2·5 Mc/s, 625, 250, 62·5 and 15·6 kc/s could be studied with a frequency resolution of 0·012 of the bandwidth. Therefore, on some occasions, our maximum frequency resolution was 190 c/s. The system temperature, including losses in the antenna feed line, was 250° K; the antenna beamwidth was 19 min of arc; coupling between the two senses of circular polarization in the antenna feed horn was approximately −15 db.

We have observed anomalously excited OH emission associated with the sources *W*3, Orion *A*, *W*49, *NGC* 6334, and the source near Sag *A* ($l^{II} = 0°\ 40'$, $b^{II} = 0°$), and found emission to be strongly circularly polarized in all cases.

We have not found any OH emission which is not circularly polarized. By contrast, our observations of OH absorption show it to be unpolarized. The spectra of the OH emission source associated with *W3* is shown in Fig. 1 and the polarization properties of the 1,665 Mc/s lines are given in Table 1. Note that many of the lines, at all four OH frequencies, exhibit 100 per cent circular polarization. Similar behaviour was noted in all the sources observed.

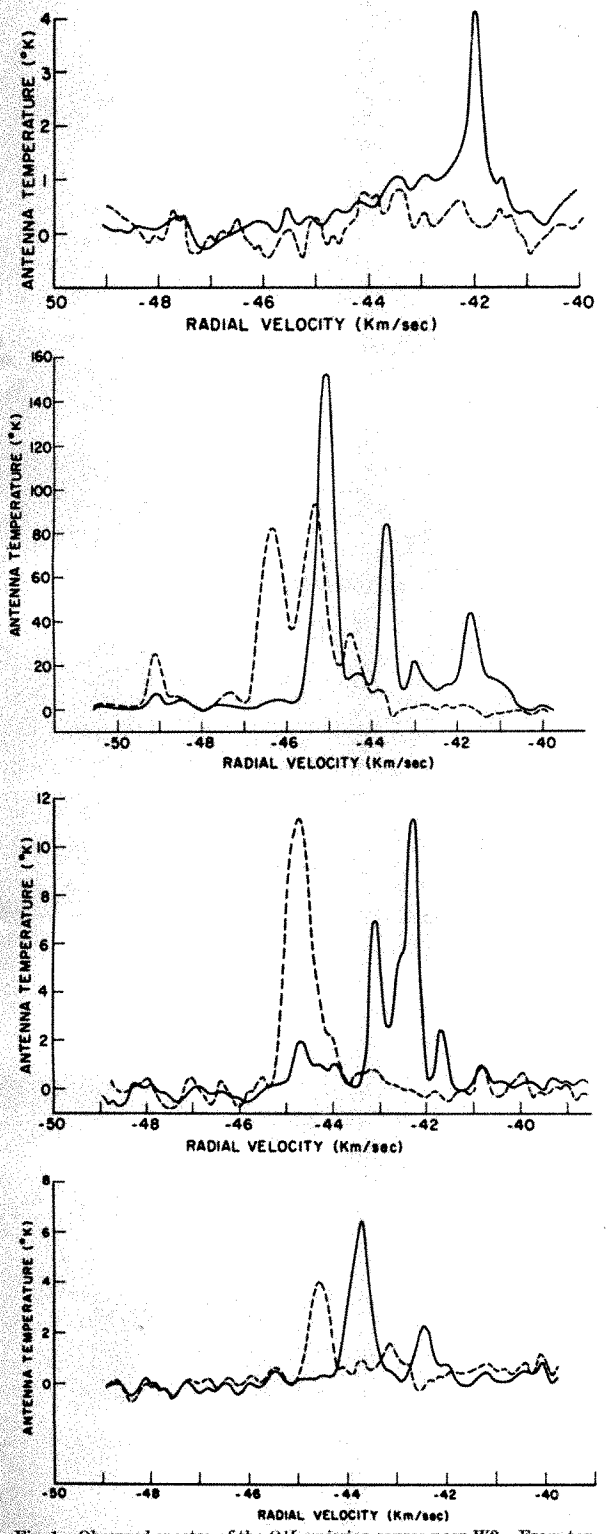

Fig. 1. Observed spectra of the OH-emission source near *W3*. From top to bottom, the frequencies are 1,612, 1,665, 1,667, and 1,720 Mc/s. The solid line shows the right-hand circularly polarized component, and the dashed line shows the left-hand. Note that the velocity scales are slightly different. The frequency resolution is 1·25 kc/s

Table 1. POLARIZATION CHARACTERISTICS OF 1,665-MC/S EMISSION FEATURES OBTAINED BY COMBINING MEASUREMENTS MADE AT HAYSTACK AND GREENBANK

Feature[1]	Velocity (OH) (km/s)	Position angle[1]	Approximate percentage polarization[5]	Comments*
1	−49·1	145° ± 10°	60	L.H. elliptical plus unpolarized radiation
2	−46·5		100	L.H. circular
3*a*	−45·5		60	L.H. elliptical plus unpolarized radiation
3*b*	−45·0		90	R.H. elliptical plus unpolarized radiation
4	−44·7	107° ± 22°	60	L.H. elliptical plus unpolarized radiation
5	−43·7	140° ± 16°	100	R.H. elliptical
6	−43·1		100	R.H. circular
7	−41·7		100	R.H. circular

* Throughout this paper, right-hand circular polarization denotes clockwise rotation of the electric vector when viewed along the direction of propagation.

Most of our observations were carried out with a frequency resolution of 1·25 kc/s and several lines were noted which appear to be inherently narrower than 1 kc/s. In particular, the −43·1 km/s line at 1,667 Mc/s in *W3* was examined with a resolution of 190 c/s and found to be approximately 600 c/s in total width, after correction for instrumental broadening. This represents the narrowest spectral line detected in radio astronomy and corresponds to a kinetic temperature of only 5° K if the width is attributed to thermal broadening. The intensity of the lines, however, argues against this interpretation.

The importance of the ability to make observations of circularly polarized emission with narrow bandwidths is clearly demonstrated by our measurements of OH near Sag *A*. McGee *et al.* have reported an emission line of 36° K intensity at +67·4 km/s when observed with 10 kc/s bandwidth at 1,665 Mc/s using a 210 ft. antenna[3]. However, when observed in left-hand circular polarization with a resolution of 1·25 kc/s using a 140 ft. antenna, this feature has an antenna temperature of 91° K, a factor of 2·5 greater than the C.S.I.R.O. observers reported even though the effective area of the antenna was a factor of 2·25 smaller. The brightness temperature of this feature must be at least 1,300° K since McGee *et al.* report an upper limit of 5 min of arc for the angular size of the OH emitting region. Other prominent emission lines detected in this source are a line of 51° K at a velocity of +73·9 km/s at 1,665 Mc/s and one line at 1,667 Mc/s with an antenna temperature of 10° K at a velocity of +69·0 km/s. The 1,665 Mc/s lines are ~100 per cent circularly polarized, the +67·4 km/s line being left-handed and the +73·9 km/s being the right-handed. The +69·0 km/s line at 1,667 Mc/s is left-hand circularly polarized but appreciably less than 100 per cent.

We find no evidence for a difference in angular size and position of the *W3 OH* source as determined by the spatial dependence of any of the emission lines at 1,665 Mc/s and 1,667 Mc/s. In our earlier communication we reported that the OH-emitting region associated with *W3* was greater than the beamwidth. This is in error. We have no evidence that any of the OH emission sources are greater than the upper limit of 5 min of arc quoted by the C.S.I.R.O. observers for *NGC* 6334 and the Sag *A* sources[3]. Also, the velocities of the 1667 Mc/s emission lines in *W3* reported earlier[1] should be increased by 0·7 km/s to read −44·8, −43·1, and −42·3 km/s in agreement with Fig. 1 of the present communication.

If it is assumed the upper limit of 5 min of arc for some of the OH-emission sources applies to *W3* also, then we must conclude from our observations that the brightness temperature of the OH at 1,665 Mc/s exceeds 2,000° K. This points out the extreme importance to be attached to an accurate determination of the angular size of these emitting regions.

Münch has reported anomalous abundances of CN molecules in the direction of the stars *BD*+66° 1675 and *BD*+66° 1674, near the HII region *W1*, and noted intensity anomalies in the CN spectra[4]. A preliminary

search revealed no OH emission in this region, but further observations should be conducted.

As noted previously, the most obvious interpretation of the existence of circularly polarized emission is the Zeeman effect. However, the presence of large intensity anomalies, the origin of which is by no means understood, makes the interpretation of our results in terms of typical Zeeman patterns exceedingly difficult, if not impossible. For example, the existence of a single line with right-hand circular polarization at 1,612 Mc/s in *W*3, without a line of the opposite sense of circular polarization being present, as shown in Fig. 1, is complotely contrary to Zeeman predictions. Even a single pair of lines at 1,612 Mc/s would be difficult to explain. Many other examples exist in our data, some of which are revealed in the *W*3 spectra of Fig. 1. We conclude that an interpretation of our observations in terms of Zeeman splittings of the lines is premature and may ultimately prove to be incorrect.

It might be possible that a maser-type amplification by the OH is occurring in the interstellar medium. This seems indicated by the intense, but very narrow, emission lines observed and by the anomalous intensity ratios between the four OH frequencies. Coherent maser amplification leads to a narrowing of the lines by an amount approximately given by $(\log_e A)^{1/2}$, where A is the power amplification factor of the medium. Therefore, amplifications of the order of 10^7 are required to narrow an emission line by a factor of 4. Furthermore, if the amplification factor is polarization sensitive, then our observations could be explained without requiring strong magnetic fields. However, it is not clear how such conditions could be produced.

We wish to express our appreciation to the entire staff of the National Radio Astronomy Observatory for their complete co-operation throughout the course of our observations. This work was supported principally by the National Aeronautics and Space Administration.

GEOPHYSICS

A Telluric Current Experiment on the Antarctic Ice Cap

A TELLURIC current recording system was installed at the Soviet station, Vostok, on the Antarctic ice cap near the South Geomagnetic Pole in December 1964. It has generally been assumed that the high resistivity would preclude such an operation. The prime difference between an ice cap installation and a land-based operation[1] lies in the electrode installation technique and the inherent high electrode-pair resistance.

The 200-m spaced electrodes consisted of 8 m by 30 cm strips of copper screen installed in a trench 30 cm deep. Several holes 2 m deep were drilled along the trench. Next the full length of the trench, the walls of the drilled holes, and the first layer of backfill were thoroughly impregnated with 100 l. of a 5 per cent aqueous solution of sodium chloride. This technique resulted in an electrode-pair resistance of 400,000 ohms, about three orders of magnitude higher than the usual land-based values[1,2]. The 200-m spacing was sufficient to produce an adequate telluric signal level.

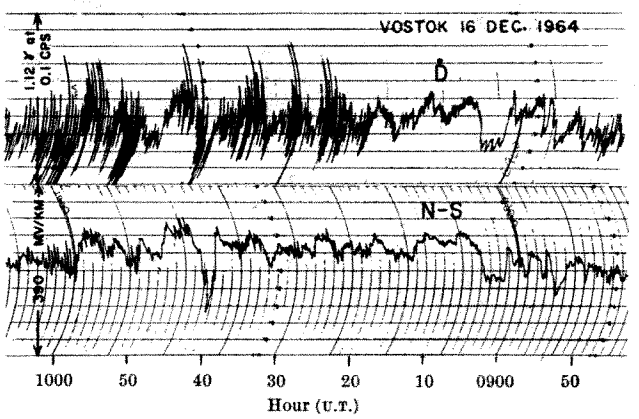

Fig. 1. North–South (in magnetic meridian) telluric current and dD/dt on the Antarctic ice cap at Vostok

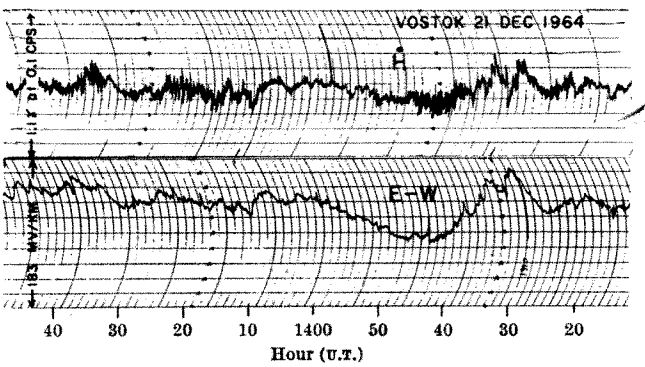

Fig. 2. East–West (perpendicular to magnetic meridian) telluric current and dH/dt on the Antarctic ice cap at Vostok

The instrumentation consisted of a 'Medistor' microvoltmeter with 1 meg input impedance and equipped with an output amplifier capable of driving the 1 mA 'Esterline Angus' recorder. The voltage gain required is indicated by the telluric signal levels shown in Figs. 1 and 2. Calibrations were made by inserting a mV signal of known value in series with one of the electrode lines, thus including the effect of the relatively high electrode-pair resistance in the calibration[1].

Figs. 1 and 2 show examples of the telluric activity and the corresponding dH/dt and dD/dt traces. The activity shown here was of more than average amplitude but characteristic of the continuing agitation observed at Vostok over a 2-week period in December 1964. This relationship between the E and H fields should be the subject of future investigation and analysis. At Vostok, on top of 12,000 ft. of a relatively good dielectric, we see that dD/dt and the North–South vector, and dH/dt and the East–West vector appear as in time phase. In contrast, over sea water on the arctic drifting stations, the same relationship holds between D and H and the corresponding electric vectors.

Telluric current recording on polar ice caps provides a useful scientific technique not hitherto available. In connexion with magnetic recordings, it permits magneto-telluric studies of the ice cap and the underlying geological structure. It provides a convenient supplementary means of studying ionospherically induced electromagnetic phenomena through a wide spectral range. It should be useful for recording the longer period P_c and P_i activity which fall in the gap which tends to exist between induction loop and normal run magnetograph records.

Readers requiring additional details of the experiment may correspond with us.

We are grateful for the Soviet invitation to work at Vostok and for the full co-operation of the station leader and staff. The magnetic data were recorded on equipment designed at the Boeing Scientific Laboratories. Dr. Pavel

Chaloupka assisted in the experiment. The research was supported by the National Science Foundation.

PHYSICS

Laser-induced Thermal Etching of Metal and Semi-conductor Surfaces

Chalmers *et al.*[1], Hendrickson and Machlin[2], and others[3–5] have demonstrated the possibility of thermally etching metals by evaporation. Thermal etching has been investigated most extensively in silver although it has been observed on other metals. It has been generally established that the etching is characterized by two mechanisms, namely, (*a*) the formation of grooves at the grain boundaries of polycrystalline metals, and (*b*) terrace or striation formation on the surface of single crystals. Grooving usually occurs at a lower temperature than that at which striation structure forms. The formation of a terrace structure, at least on the surfaces of copper and silver single crystals, may depend on the presence of oxygen during annealing. This communication reports a further consequence of thermal etching in air, namely, the formation of etch hillocks. This phenomenon has now been established for a number of metals and semiconductors.

Thermal etching was carried out by focusing the output of a ruby laser on to the surface of the material under investigation. The laser used was a commercial unit operating in the *Q*-switched mode. The output pulse had a width of about 80 nsec and a peak power of about 5–6 MW. The pulse was focused on to the surface with a 1·95 cm focal length lens. The surface was polished either mechanically or chemically and was subjected to only one pulse. This process usually produced a superficial crater with a diameter of about 1–2 mm. The etched area was then replicated using the selected area technique described by Fourie[6]. The replica is a shadow-cast primary replica suitable for investigation by transmission electron microscopy. In order to determine whether the laser-produced surface structures were pits or hillocks, it proved necessary to prepare a second replica of the same area. This was then sprayed with a dilute solution of polystyrene latex particles in water. The dried replica was then shadowed and coated with carbon as before. A comparison of the directions of the shadows of the latex and feature then determined the type of feature. That there were hillocks present could also be shown by making a 'through-focus' observation on the original metal surface with a high-powered optical microscope.

Typical etch patterns observed in a number of materials are shown in Figs. 1 and 2. The micrographs are of replicas of regions close to the crater periphery where it has been possible in some cases to compare surface structure as a result of deformation with the resulting etch features inside the crater.

Fig. 1*a* shows a thermally etched region on a (111) plane of a copper single crystal. The etched ridges lie along the <110> direction. This terraced structure is typical of copper crystals thermally etched in an oxygen-rich environment (compare Ponslet and Bariaux[7]). Fig. 1*d* shows a typical region on the surface of an etched α-brass single crystal (20 per cent zinc). The sample had been plastically deformed by uniaxial tension prior to the etch. The hillocks are clearly located along slip lines, a number of which are still visible. In Fig. 1*c* the crater edge in body-centred cubic iron is shown. The hillocks seem to lie along a continuation of the surface deformation markings. Note the very gradual slope into the crater. Van Wijk and Van Dijck[8] have observed similar hillocks in chemically etched iron and have associated these with dislocations in the sample[9]. Fig. 1*d* shows small etch hillocks inside a grain of polycrystalline platinum.

Figs. 1*e* and *f* are examples of laser-induced etching on the surface of polished gallium-arsenide and germanium, respectively. In Fig. 1*f* the features marked *B* are etch pits, while the fine features in the background are a mixture of etch hillocks and pits. The gallium-arsenide used in Fig. 1*e* was *p*-type arsenic-rich material with a

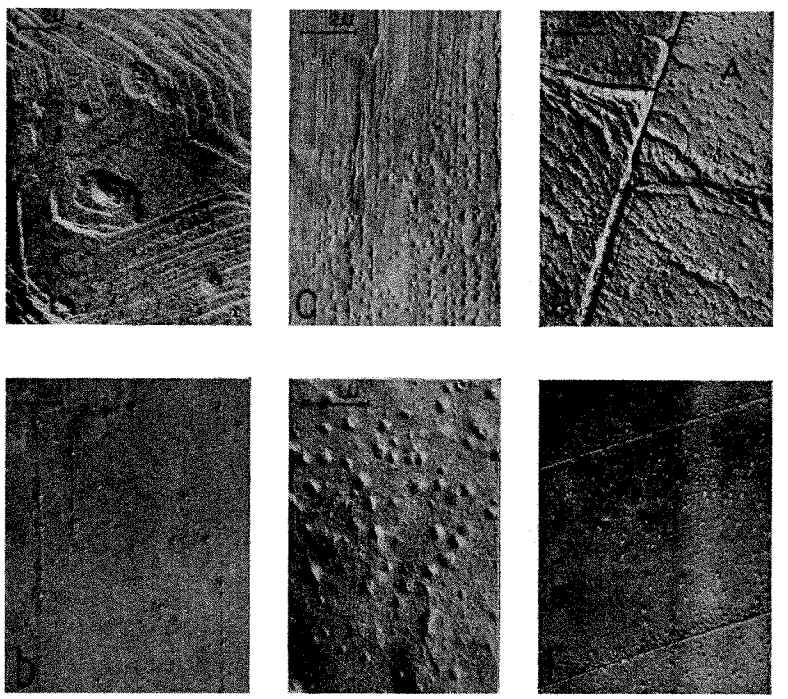

Fig. 1. Electron micrographs of thermal etch patterns. (*a*) Copper; (*b*) 20 per cent zinc α-brass; (*c*) iron; (*d*) platinum; (*e*) gallium-arsenide; (*f*) germanium

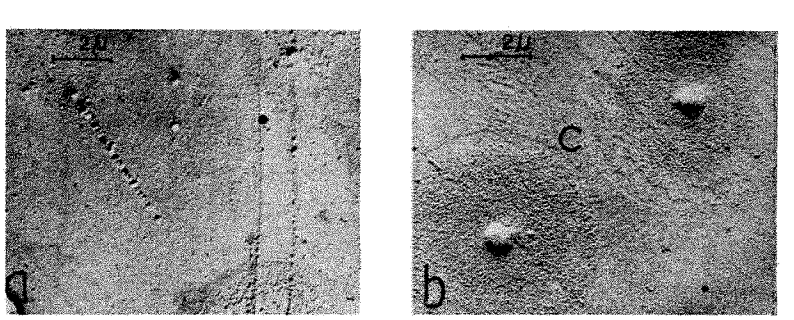

Fig. 2. Surface structure of a laser-etched α-brass crystal

specific conductivity of $2{\cdot}2 \times 10^{-3}$ ohm^{-1} cm^{-1}. This sample showed marked grooving along the grain boundaries as well as a high density of large hillocks (marked *A*). The background, in common with germanium, is a mixture of fine etch pits and hillocks.

We have further established that hillocks appear when aluminium, silver, nickel and molybdenum are thermally etched with laser radiation. Apart from the iron which has a purity of 99·98 per cent, the other materials used in this investigation are spectroscopically pure.

The correspondence of etch hillocks and crystal substructure is still being investigated. Fig. 2*a* is an example of a possible dislocation pile-up in a 20 atomic per cent zinc α-brass crystal. A number of such features have been observed in this alloy. The hillocks in these clusters are usually of the same radial size. We have also observed a number of very large hillocks ; these are usually isolated, although centred on a common slip line with small hillocks. Fig. 2*b* shows the characteristic appearance of two such hillocks. Note the rim structure at *C*. These large hillocks are similar in appearance to those observed in copper (Fig. 1*a*).

The development of etch hillocks, as described here, might be a result of the unusual method used to produce the thermal etching. The method appears to have many general applications ; for example, as laser radiation can be focused through a window, the thermal etching of a metal surface which is both under high vacuum and at a low ambient temperature is now possible.

Light Emission in *n*-Hexane under High Electric Stress

LIGHT emission, resulting from the application of high d.c. fields, has been reported for insulating liquids containing fluorescent materials in solution[1,2], and for *n*-hexane by us[3]. Further, a change of refractive index has been observed between electrodes in hexane when a voltage pulse was applied across them[4].

All indications are that the phenomena commence at the cathode, and it is the purpose of this communication to report some further observations on the form of the light emission from the cathode in *n*-hexane resulting from the application of high d.c. fields.

The test cell, electrode systems and cleaning techniques were similar to those adopted by Kao and Calderwood[5] but the *n*-hexane was used as supplied without further treatment. The cathode was a steel gramophone needle having a point radius approximately 0·02 mm and the anode was a stainless steel sphere of 0·25-in. diameter. The background to the electrodes could be illuminated with a pre-focus lamp of adjustable intensity directed through the electrode gap in the test cell towards the lens which focused on the image intensifier which has been described[6]. The output screen of the image intensifier was observed visually and also photographed with a 'Polaroid' camera.

Fig. 1 shows two typical examples of weak light-emission observed at 24·5 kV and 30 kV with a gap length of 1·75 mm. The bright ring* was clearly visible on the screen although it only lasted for a short time: it originated from the tip of the point cathode. This phenomenon can be repeated experimentally. The outlines of the electrodes have been superimposed on the photographs for clarity.

a *b*

Fig. 1. Light emission in *n*-hexane under high electric stress. Gap length = 1·75 mm. (*a*) Applied voltage; 24·5 kV; (*b*) applied voltage; 30 kV

It would be reasonable to assume that a copious supply of electrons is available at the point cathode for the fields under investigation. The electrons may gain energy, excite molecules and form ions with subsequent light emission from the plasma region.

Initially the region of plasma is very small and the electric field at its front boundary is very large. As the plasma grows, this field tends to decrease since the plasma acts as an electrode of increasing effective radius: however, the field eventually begins to increase due to the decreasing effective gap length. Assuming that this explanation holds, the photographs obtained by us could be interpreted as being photographs of the plasma region. Since breakdown did not follow immediately on the event photographed, it must be assumed that the electric field at the front of the plasma had dropped to such a value that it was insufficient to propagate the plasma.

CHEMISTRY

Boron Carbide, a New Substrate for Fuel Cell Electrocatalysts

A NUMBER of investigators have reported high-performance, direct hydrocarbon fuel cells[1–4]. In every case, the direct hydrocarbon anode has used a large amount of high-area platinum black or Raney platinum in the range of about 10–100 mg/cm^2 of geometric electrode area. This tends to counteract the advantage of being able to operate on inexpensive hydrocarbon fuels. Furthermore, there is a tendency for performance to be proportional to

platinum content. Niedrach[5] has shown that 'Teflon'-bonded electrodes[6] containing mechanical mixtures of platinum black with tantalum or platinum deposited on tantalum give performance on propane which is just proportional to the platinum content. Thus, the advantage of reduction in platinum content is cancelled out by the reduction in performance.

In conventional catalysis, catalytic materials are often supported in order to attain high surface area, retard sintering, and achieve high activity per unit weight. In a number of instances, the catalytic activity of transition metals has been found to vary with the nature of the support material[7–10]. In supported electro-catalysis, carbon has been so widely used as a support, and diversification to other materials has been so limited that the question of whether a suitable support material might markedly enhance electrocatalytic activity remains unanswered.

This communication reports the first results[11] obtained with hydrocarbon fuel cell anodes containing boron carbide as the support for platinum electrocatalyst. The results indicate that an enhancement of platinum activity has been achieved when compared with an equal weight [illegible] an equal hydrogen adsorption surface area of platinum black. As a support boron carbide appears to be interesting [illegible] other ways as well. Platinum on boron carbide was found to be more resistant to sintering than platinum black or platinum on graphite at equal surface coverage. Also, the catalysed adsorption of hydrogen on to a graphite support[12] was found to be absent in the case of boron carbide. These results suggest interesting and probably useful features of boron carbide over and above its well-known properties of corrosion resistance and oxidative stability.

To prepare the supported platinum a commercial boron carbide powder ('Norbide' abrasive, Norton Co., Worcester, Mass.) was activated by slurrying it with a solution of platinum diammine dinitrite, driving off the solvent by heating and then reducing in hydrogen at an elevated temperature. The comparison platinum black was of commercial origin (platinum black 100 per cent, Engelhard Industries, Newark, N.J.). The materials were made into 'Teflon'-bonded electrodes of a previously described structure[6]. Surface areas of the electrocatalysts were obtained as follows.

The total surface area was determined by the Brunauer–Emmett–Teller method using the adsorption of nitrogen at −195° C. The area of the supported platinum was determined by measurements of the chemi-sorption of hydrogen at 200° C, the sample having been previously reduced and then evacuated at this temperature. The effective area of the metallic phase was calculated by assuming that each chemisorbed hydrogen atom occupied one surface metal site.

The results of typical adsorption measurements are shown in Table 1. The highest degree of metallic dispersion was obtained with low platinum loadings and low reduction temperatures. The average platinum crystallite size calculated from the adsorption measurements agreed well with estimates made from electron micrographs of the samples. For purposes of comparison a commercial platinum black has a surface area of about 20 m²/g and particle size of about 100 Å diameter.

Performance of the test anodes on propane fuel was evaluated in complete fuel cells containing similar platinum black oxygen cathodes. Phosphoric acid (85 per cent by weight) was the electrolyte, and the temperature was 150° C. The current density maintained at an *iR*-free cell potential of 0·5 V (corresponding to an anode potential of 0·42 V versus a reversible hydrogen electrode in the same electrolyte) was taken as a performance index.

Table 1. PROPERTIES OF Pt–B₄C CATALYSTS

Wt per cent platinum	Hydrogen adsorbed (ml. S.T.P./g)	Surface area of platinum (m²/g platinum)	Total metal area (m²/g sample)	Platinum crystallite size (Å)
0	0·041	—	—	—
0·5	0·197	149	0·75	16
2·0	0·310	65·3	1·31	36
4·8	0·679	63·5	3·05	38
9·1	1·007	50·7	4·61	47

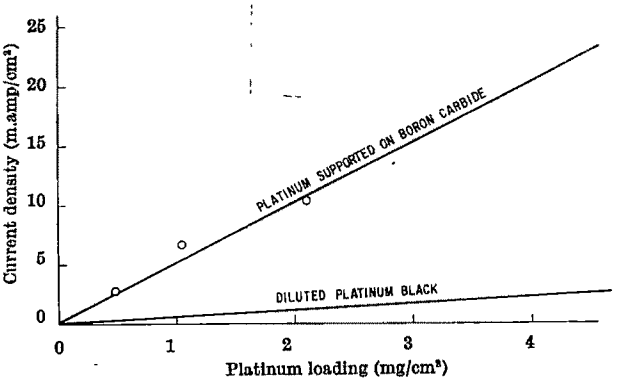

Fig. 1. Current density at cathode versus anode voltage = 0·5 (anode versus reference voltage = 0·42) V versus platinum loading for platinum supported on boron carbide and platinum black diluted with boron carbide; propane-oxygen cells, 150° C, 85 per cent phosphoric acid electrolyte

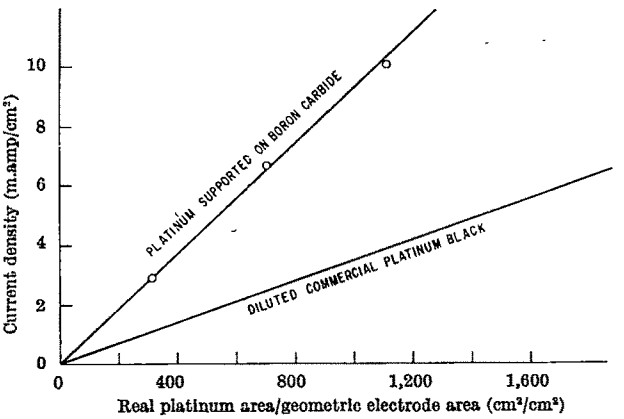

Fig. 2. Current density at cathode versus anode voltage = 0·5 (anode versus reference voltage = 0·42) V versus real platinum area per unit electrode area for platinum supported on boron carbide and platinum black diluted with boron carbide; same operating conditions as for Fig. 1

This index is plotted against platinum weight per unit electrode area in Fig. 1. The best straight line through three data points and the origin gives a slope indicating the effectiveness of the platinum in m.amp/mg platinum. The same effectiveness factor for platinum mechanically diluted with boron carbide is shown by the lower line in Fig. 1. The slopes are 5 m.amp/mg for platinum on boron carbide and 0·6 m.amp/mg for platinum black diluted with boron carbide, an improvement of a factor of 9. This is partly due to a higher platinum surface area for the supported platinum. In Fig. 2, the fuel cell performance index is plotted against the real platinum surface area per unit electrode area. These data fit a straight line better. Again the line for mechanically diluted platinum black is included for comparison. The slopes now give current density per square centimetre of real platinum area and the values are 9·3 and 3·5 μamp respectively. This factor of improvement could indicate enhancement of platinum activity by the support.

Further experimental effort is required to confirm this last conclusion. Nevertheless the results so far indicate that boron carbide is an interesting support for catalysts and electrocatalysts, and further investigation is under way.

We thank Dr. L. W. Niedrach for helpful discussions and for permission to cite unpublished data. This work

is a part of a programme under contracts with the U.S. Army Engineer Research and Development Laboratories, Fort Belvoir, Virginia, to develop a technology which will facilitate the design and fabrication of practical military fuel cell power plants for operation on ambient air and hydrocarbon fuels.

Frequency Assignments in Infra-red Spectrum of Water

ALTHOUGH the infra-red spectra of water and deuterium oxide vapour have been carefully mapped and satisfactorily analysed, the infra-red spectrum of water in the liquid state possesses many features that are still not clearly understood. As in the case of most liquids, the near-infra-red spectrum of the liquid is characterized by strong bands in the same spectral regions as those in which the strong vibration–rotation bands of the vapour occur. However, in the case of liquid water there are additional weaker near-infra-red bands that have no counterparts in the water-vapour spectrum. This communication offers a tentative assignment of these near-infra-red 'associational bands' in terms of monomeric vibrational modes and certain lattice modes reported recently by Draegert *et al.*[1], who have investigated the far-infra-red spectrum of liquid water between 30 cm^{-1} and 1,200 cm^{-1}.

In a report of their own recent work, Bayly *et al.*[2] have included a useful summary of numerous earlier experimental investigations of the near-infra-red spectrum of liquid water and have discussed the various attempts at making frequency assignments for the observed bands. The strong liquid-water bands in the near-infra-red and their interpretations are as follows: (1) a relatively narrow band at 1,630 ± 15 cm^{-1}, which is attributed to the ν_2 bending mode of the water monomer; (2) an extremely broad and intense band with maximum absorption at 3,430 ± 60 cm^{-1}, which is mainly attributed to the asymmetric valence vibration ν_3 of the monomer but also involves $2\nu_2$ and the normally infra-red inactive symmetric valence vibration ν_1; (3) a broad band at 5,140 ± 60 cm^{-1}, which is attributed to the combination $\nu_2 + \nu_3$. The indicated value of the frequency listed for each band is the average of the values obtained in the various investigations summarized by Bayly *et al.*[2], and the indicated uncertainties cover the range of values obtained in these independent investigations.

The best known of the associational bands of water is a broad band with frequency $\nu_x = 2{,}130 \pm 5$ cm^{-1}, which has been extensively investigated. Additional weaker associational bands $\nu_y = 3{,}950 \pm 30$ cm^{-1} and $\nu_z = 5{,}600 \pm 20$ cm^{-1} have been reported by Collins[3], Ellis[4], and others[2,5,6].

In liquid deuterium oxide the corresponding strong bands are: (1) $\nu_2 = 1{,}218 \pm 3$ cm^{-1}; (2) $\nu_3 = 2{,}514 \pm 30$ cm^{-1}; and (3) $\nu_2 + \nu_3 = 3{,}815 \pm 15$ cm^{-1}. The associational bands in liquid deuterium oxide are: $\nu_x = 1{,}555$ cm^{-1}, $\nu_y = 2{,}900$ cm^{-1}, and $\nu_z = 4{,}100$ cm^{-1}. Only Bayly's values are listed for the deuterium oxide associational bands, as work by others has not been extensive; although Bayly did not state uncertainties in frequency, it is possible that they may be comparable with those stated previously for the water associational bands. It is to be noted that the ratio of the frequencies of the water bands to the frequencies of the corresponding deuterium oxide bands is in every case approximately 1·35.

Various attempts[2] have been made to account for the near-infra-red associational bands in terms of combinations of the monomeric vibration modes with a single hypothetical infra-red-active mode producing a band in the far-infra-red. However, no experimental evidence of a band with the proposed frequency has been obtained.

The results reported by Draegert *et al.* form the basis for a more realistic assignment of the near-infra-red associational bands. For liquid water these authors report a broad major band with maximum absorption at 685 ± 15 cm^{-1} together with a second less-intense overlapping band at 170 ± 15 cm^{-1}. In liquid deuterium oxide, the corresponding bands appear at 505 ± 15 cm^{-1} and 165 ± 15 cm^{-1}, respectively. The ratio of the frequency of the major far-infra-red band in water to that of the corresponding band in deuterium oxide is 1·35—a value identical with the corresponding ratio obtained for the near-infra-red bands. Thus, it would appear that the major bands can be attributed to some molecular motion that is influenced by isotopic substitution to the same extent as the vibrations responsible for the near-infra-red bands. Since the hindered rotation of water and deuterium oxide molecules in the liquid lattice would satisfy this requirement, the major far-infra-red bands are tentatively assigned to a hindered-rotation mode ν_R.

The minor far-infra-red bands in liquid water and deuterium oxide have nearly the same frequency and therefore have an origin quite different from those of the other infra-red bands. It is probable that translational motion of entire monomeric units of water and deuterium oxide are involved. Welsh *et al.*[7] have shown that even for non-polar molecules translational absorption can occur during collisions; the collision-induced electric dipole moment provides the mechanism for interaction with the radiation field. The production of induced dipole moments during collisions between molecules is quite general except for like molecules having spherical symmetry. Ewing and Trajmar[8] have demonstrated the existence of quantized translational states of a molecule within a shell formed by its neighbours. It is therefore suggested that the minor far-infra-red bands in water and deuterium oxide be attributed to a translational mode ν_T and that they involve a transition from the lowest to the first excited translational level.

With the far-infra-red bands designated as ν_R and ν_T it is proposed that the weak associational bands in the near-infra-red involve absorption of radiation by molecules initially in the first excited translational energy state. Thus the following assignments are proposed: $\nu_x = \nu_3 + \nu_R - \nu_T$, $\nu_y = \nu_3 + \nu_R - \nu_T$, and $\nu_z = \nu_2 + \nu_3 + \nu_R - \nu_T$. Comparisons of the observed values of ν_x, ν_y and ν_z with values predicted on the basis of the proposed assignments are given in Table 1. In view of the uncertainties in the

Table 1. OBSERVED AND PREDICTED FREQUENCIES OF ASSOCIATIONAL BANDS

Band	Frequencies (cm^{-1})			
	H_2O		D_2O	
	Obs.	Pred.	Obs	Pred.
ν_x	2,130	2,145	1,555	1,558
ν_y	3,950	3,945	2,900	2,854
ν_z	5,600	5,575	4,100	4,072

frequencies of the near-infra-red bands, the agreement between observed and predicted values is quite good. For water, agreement with the data of Ellis and Sorge is nearly perfect, and for deuterium oxide agreement with Bayly *et al.* is excellent; however, in the interests of objectivity, the frequencies listed in the table are based on mean values of published results. It is interesting to note that the frequency difference $\nu_R - \nu_T$, which appears in all assignments for the associational bands, is exactly the required frequency of the hypothetical band proposed by earlier workers.

Although the suggested frequency assignments fit the existing data quite well, it is obviously necessary to establish definitely the mechanisms involved in the ν_T and ν_R modes and to consider further the processes involved in absorption by molecules in excited translational energy states. Further work on these subjects is at present in progress.

BIOCHEMISTRY

Antigenic Properties of Soluble Elastins and their Use in Detecting Soluble Elastin in Ligament Extracts

IN this laboratory we have been interested in the existence of a possible soluble precursor of insoluble elastin (tropoelastin) analogous to tropocollagen. However, since elastin has no enzyme activity and does not possess a specific amino-acid, such as occurs in collagen, no simple method was available to detect this protein in the presence of large amounts of other proteins, which are found in tissue extracts.

We therefore turned our attention to the antigenic properties of elastin in order to use immunochemical methods to detect its soluble precursor. Previous reports[1-3] indicated that elastin was in fact non-antigenic. However, we were informed by Dr. S. M. Partridge (personal communications) that his group had succeeded in developing antibodies against α-elastin (a soluble product of partial hydrolysis of elastin), but the specificity of their anti-sera was questionable. More recently Robert *et al.*[4] have described the development of rabbit antibodies against high molecular weight peptides obtained by alcoholic potassium hydroxide digestion of bovine aortic elastin (κ-elastin)[5].

Alpha elastin was prepared in our laboratory from adult bovine ligamentum nuchae by partial hydrolysis of purified insoluble elastin with 0·25 M oxalic acid[6] followed by de-ionization on a 'Dowex' resin column[6]. A 2 per cent saline solution of the α-elastin was thoroughly mixed to an emulsified state with equal parts of a complete Freund's adjuvant. This emulsion was injected weekly into rabbits using 1 ml., subcutaneously, in four divided doses over the back. After 5 weeks, a very weak precipitin reaction was detected using the serum of all three immunized animals. A prozone phenomenon could not be documented. Primary immunization was continued for a total of 7 weeks. The animals were allowed to rest for 2 months, and a series of four secondary injections were given at weekly intervals. A weak precipitin reaction was again detected. This was insufficient to quantitate but appeared somewhat stronger than that noted during the primary response. The immune response of one of the test rabbits is reported in detail for primary as well as repeated secondary stimulation (Table 1).

This technique, including 2 months of rest between injections, was repeated two additional times. This gave distinct precipitin reactions with a maximum amount of precipitate at a 0·5 and 0·25 mg/ml. concentration of the antigen when reacted with the undiluted rabbit anti-serum. Precipitates were not apparent until the reaction mixture had been allowed to incubate in the cold overnight. Precipitins were never of a marked flocculent nature. Although areas of antigen and antibody excess were apparent, the exact zone of optimal proportions in a serial dilution of the antigen was difficult to delineate (Table 1). Precipitin bands by Ouchterlony diffusion[7] were not distinct. Only one band was seen and the sharpest band appeared to be at 0·125 mg/ml. antigen concentration when reacted with undiluted rabbit anti-serum. It was suspected that we were dealing with a system in which the antigen–antibody complex existed largely in the soluble state.

Results were more uniform with immunoelectrophoretic techniques[8]. Using large quantities of sera in repeated application, which was necessary to give visible results, one diffuse band was obtained when the original antigen was reacted with the anti-serum from any one of the three test rabbits. All control sera obtained from these rabbits prior to primary immunization were negative, as well as attempted cross-reactions with bovine serum and collagen. Alpha elastin prepared from foetal bovine ligamentum nuchae was reacted against the anti-sera from all three animals, and gave a reaction similar to that obtained with the original antigen.

Antigen–antibody interaction was also demonstrated by passive cutaneous anaphylaxis using guinea-pigs. Strongly positive tests were obtained with undiluted and 1:10 dilutions of the anti-sera.

Haemagglutination studies were carried out using formalinized, tanned, red blood cells to quantitate and

Table 1. PRECIPITATING ANTIBODY RESPONSE OF RABBIT AFTER REPEATED INJECTIONS OF 2 PER CENT α-ELASTIN WITH EQUAL PARTS OF FREUND'S ADJUVANT

Undiluted rabbit anti-sera plus	Antigen concentrations (mg/ml.)

Primary response—1st and 2nd month	+/−	+/−	+/−	1+	1+	+/−	+/−	−	−
Secondary responses									
Set 1 — 5th month	+/−	+/−	+/−	1+	+/−	+/−	+/−	−	−
Set 2 — 7th month	+/−	+/−	1+	1+	+/−	+/−	+/−	−	−
Set 3 — 9th month	+/−	1+	2+	2+	1+	+/−	+/−	−	−
Set 4 — 11th month	1+	2+	2+	1+	1+	+/−	−	−	−

Precipitin tests were read after incubating at 37° for 1 h and then in cold for 18 h.

characterize the antigen–antibody reaction already demonstrated. Type 0, Rh positive human cells collected in Alsevers solution were formalinized after the method of Butler[10]. A 4 per cent solution of these cells was incubated with an equal volume of fresh 1:20,000 tannic acid solution for 30 min at room temperature. After washing three times with *p*H 7·4 phosphate-buffered normal saline, a 2 per cent saline suspension was made, and 5-ml. aliquots were quick frozen in liquid nitrogen. Aliquots were stored in this state until used for haemagglutination investigations. Immediately before testing, sufficient quantities of the cells were thawed and incubated at room temperature for 1 h with equal volumes of the serially diluted α-elastin solution. After three washes with a 1:200 normal rabbit serum in buffered saline, 0·1-ml. portions of the coated, tanned, cell suspension, in 2 per cent concentrations, were mixed with an equal volume of the serially diluted anti-serum. The presence of haemagglutination was read after incubation for 3 h at room temperature. All tubes were reshaken and read again after a total incubation time of 12-18 h. Sharper readings were obtained after 12 h, with controls more uniform.

Haemagglutination scoring was read in a fashion similar to that of Stavitsky[11]. Marked 4+ reactions were obtained with 1·0 and 0·5 mg/ml. concentrations of the antigen and a 1:50 dilution of the anti-serum. Haemagglutination was evident at dilutions down to 0·125 mg/ml. of antigen using this same concentration of anti-serum. Table 2 summarizes representative results of the haemagglutination studies. Collagen was found to interfere with haemagglutination studies. All tubes, including control antigen tagged cells without anti-sera, gave 1+ readings. However, incubation at +4° C rather than at room temperature prevented this non-specific agglutination phenomenon. Strong positive cross-reactions were obtained when the anti-serum was incubated with the κ-elastin of Robert[4] and the α-elastin from foetal tissue. The foregoing results indicated a strong antigen–antibody reaction with specificity.

Table 2. HAEMAGGLUTINATIONS OBSERVED WHEN α-ELASTIN WAS REACTED WITH ANTI-α-ELASTIN. READING MADE AFTER 12-H INCUBATION AT ROOM TEMPERATURE

Concentrations of α-elastin incubated with formalinized, tanned, red cells (mg/ml.)

Anti-alpha elastin	2·0	1·0	0·5	0·25	0·125	0·0625	0·031	Control formalinized, tanned, red cells
1·50	4+	4+	3+	2+	1+	–	–	–
1 250	2+	1+	1+	+/–	–	–	–	–
1:1250	+/1	–	–	–	–	–	–	–
Saline control	–	–	–	–	–	–	–	–

On the basis of previous work carried out in our laboratory[12], extracts were made of term foetal bovine ligamentum nuchae using a *tris*-HCl buffered normal saline solution at *p*H 8·4. Because of the interference noted earlier, collagen was precipitated from this extract by adding cold absolute ethanol to a total volume of 20 per cent. Ethanol was removed by dialysis. Haemagglutinations were then carried out at +4° C using the ligament extract as antigen and the anti-alpha elastin as antibody. Strong cross-reactions were observed. Table 3 summarizes these results.

Table 3. HAEMAGGLUTINATIONS OBSERVED IN A 20 PER CENT ETHANOL-TREATED EXTRACT OF FOETAL BOVINE LIGAMENTUM NUCHAE WHEN REACTED WITH ANTI-α-ELASTIN. READINGS MADE AFTER 3-H INCUBATION AT +4° C

Concentrations of extract incubated with formalinized, tanned, red cells (mg/ml.)

Anti-α-elastin dilutions	2·0	1·0	0·5	0·25	0·125	0 062	0·031	Saline control
1:50	4+	4+	3+	3+	2+	1+	–	–
1:100	3+	4+	3+	3+	1+	–	–	–
1.200	2+	3+	3+	2+	1+	–	–	–
Saline control	–	–	–	–	–	–	–	–

These ligament extracts were used in another study to immunize rabbits using the same régime as that described for α-elastin. The anti-sera obtained were found to cross-react with the α-elastin using the haemagglutination technique with formalinized, tanned, red cells and also the passive cutaneous anaphylaxis test. No cross-reactions were detected, however, by Ouchterlony diffusion or immunoelectrophoresis using these same anti-sera.

The availability of an anti-serum to α-elastin together with the haemagglutination technique described provides an amply sensitive method of specifically detecting small amounts of soluble elastin in the presence of other proteins. This method has been used in this laboratory to detect the presence of soluble elastin in fractions obtained by chromatography of extracts of bovine foetal ligamentum nuchae.

Excretion of Xanthurenic Acid in the Urine of Women taking Progestogen–Oestrogen Preparations

THE purpose of this communication is to report the excretion of grossly increased amounts of xanthurenic acid in the urine of women taking a combination of a progestogen and an oestrogen for contraceptive purposes, following a tryptophan load.

Fourteen women taking various oral contraceptive preparations were investigated. An oral load of L-tryptophan (5 g) was given. All the urine passed during the subsequent 8 h was collected, the volume measured, and an aliquot kept at −20° C until the estimation was made. Xanthurenic acid was estimated by the paper chromatographic method of Coppini, Benassi and Montorsi[1], except that the solvents used were *n*-butanol/acetic acid/water (12:5:3) followed by *n*-butanol/pyridine/water (1:1:1). The results have been expressed as mg of xanthurenic acid excreted in the 8 h period following the tryptophan load. The excretions for 12 normal subjects (six males and six females) ranged from 10 to 60 mg. The authenticity of the presumed xanthurenic acid spots on the chromatograms of urine was established by comparing the R_F values and colour reactions with those of a xanthurenic acid marker (Table 1). The high excretions were dependent on the administration of a tryptophan load, and were maximal 4–5 h after giving the tryptophan.

Table 1. CHROMATOGRAPHIC CHARACTERISTICS OF XANTHURENIC ACID

	R_F values from two-dimensional chromatography				Colour reactions			
	BuA	BuP	KCl	IPrAm	UVL	SuA	Ehrlich	FAS
Authentic xanthurenic acid	0·60	0·63	0·22	Very little movement, tailing of spot	Bright blue	Red	Nil	Green
Presumed xanthurenic acid in urine	0·60	0·63	0·23	Ditto	Bright blue	Red	Nil	Green

BuA = *n*-butanol/acetic acid/water (12 : 5 : 3). BuP = *n*-butanol/pyridine/water (1 : 1 : 1). KCl = 20 per cent potassium chloride. IPrAm = isopropanol/ammonia/water (20 : 1 : 2). UVL = ultra-violet light. SuA = diazotized sulphanilic acid. Ehrlich = *p*-dimethylamino benzaldehyde 2 per cent in 1·3 N HCl. FAS = 1·7 per cent ferric ammonium sulphate followed by 5 per cent $NaHCO_3$. All chromatographs carried out on Whatman No. 1 paper.

The results obtained for the 14 women taking progestogen–oestrogen preparations are given in Table 2. The excretion of xanthurenic acid in the urine of subject 10 was re-estimated after the oral administration of pyridoxine hydrochloride (40 mg) daily for 5 days. The output had fallen from 593 mg to 80 mg in an 8 h collection of urine.

Table 2. URINARY EXCRETION OF XANTHURENIC ACID: WOMEN TAKING PROGESTOGEN–OESTROGEN PREPARATIONS

Subject No.	Preparation (daily dose)	Duration of use	Xanthurenic acid excretion (mg in 8 h)
1	*Nor*ethisterone acetate 3 mg Ethinyl oestradiol 0·05 mg	3 years	983
2	,, ,, ,,	18 months	144
3	,, ,, ,,	12 months	155
4	,, ,, ,,	11 months	407
5	,, ,, ,,	3 days	79
6	*Nor*ethisterone acetate 4 mg Ethinyl oestradiol 0·05 mg	4 months	530
7	*Nor*ethisterone 2 mg Ethinyl oestradiol-3-methyl ether 0·1 mg	2 months	211
8	,, ,, ,,	2 months	181

14	,, ,, ,,	1 month	24

Increased excretions of xanthurenic acid and other tryptophan metabolites have been reported in pregnancy, and have been interpreted as indicating pyridoxine deficiency[2,3]. Brown, Thornton and Price[4] confirmed these observations, but found the output of kynurenic acid to be decreased in pregnancy, whereas in simple pyridoxine deficiency the excretion of this metabolite is also raised. They suggested that the excretion pattern of the tryptophan metabolites in pyridoxine deficiency is modified by the hormonal changes of pregnancy. This view is supported by the demonstration that sulphate esters of oestrogens inhibit the *in vitro* activity of rat kidney kynurenine transaminase, the enzyme concerned in the formation of kynurenic acid from kynurenine. The abnormal excretions of xanthurenic acid, following a tryptophan load, by women taking progestogen–oestrogen preparations may be explained by a similar mechanism. The marked fall in the excretion of xanthurenic acid by the subject treated with pyridoxine suggests that the hormonal effect may result from interference with the coenzyme function of pyridoxal-5-phosphate. Further investigations are being carried out to explore this hypothesis.

Amino-acid Composition of the Acquired Pellicle of Human Tooth Enamel

AFTER eruption human teeth acquire a structureless film, tenaciously attached to the enamel surface, which may be liberated from clean, debris-free, healthy teeth by immersion in a solution of strong mineral acid. This acid-insoluble cuticular structure has been given various names by different authorities, and in a review of the confused nomenclature on this subject it was recommended that the term 'acquired pellicle' be used[1]. Various possible origins for this pellicle layer have been proposed, and while it has usually been assumed that it is most probably of salivary origin it has also been considered that it may be (*a*) a horny keratinous layer formed from oral epithelium[2]; (*b*) the remains of a collagenous cementum-like layer over the occlusal surface of the teeth[3]; (*c*) dental plaque which had become structureless due to lysis of its bacteria[4]. A recent suggestion is that it may be derived from denatured haemoglobin[5].

In an attempt to clarify the nature of the acquired pellicle, material was collected, hydrolysed and subjected to quantitative amino-acid analysis using a Technicon automatic amino-acid analyser. The results from analysis of three different pooled preparations of acquired pellicle are given in Table 1, where they are compared with an analysis of crude human salivary mucin.

Table 1 COMPOSITION OF ACQUIRED PELLICLE ON HUMAN TOOTH ENAMEL

Component	Acquired pellicle hydrolysates (1)	(2)	(3)	Human salivary mucin hydrolysate
Aspartic acid	76·60	70 09	67·75	83 61
Glutamic acid	141·15	136·00	132·31	126·69
Threonine	44·07	40 47	41·98	57·29
Serine	44·07	43·39	49·15	76 85
Proline	45·65	41·72	44·63	55·19
Hydroxyproline	0	0	0	0
Alanine	150 58	141·84	142·67	75·92
Glycine	82·37	81·35	82·09	96·41
Valine	50·37	63·83	45·70	51·47
Iso-leucine	33 05	30·87	28·96	38 66
Leucine	66·11	72·17	64·29	85·47
Tyrosine	17·84	20·44	20·72	26·55
Phenylalanine	27·25	28·37	26·83	32·60
Ornithine	28 35	25 45	28·16	6·75
Lysine	52 47	55·07	61·11	61·71
Hydroxylysine	0	0	0	0
Histidine	17·84	27·53	27·10	19 10
Arginine	50·85	40 47	37·73	45·18
Cysteine	0	0	0	0
Methionine	0	0	0	0
Hexosamine	41·45	40·88	48·09	21·19
Muramic acid(?)	20·45	20 86	20·49	0
Unknowns	9·44	19·19	30 31	39·36

All results are expressed as residues per 1,000 residues. Unknown components were calculated as *nor*-leucine equivalents.

The three different hydrolysates of acquired pellicle show a fairly close agreement, indicating that the structure is probably derived from material with a characteristic constant composition. Distinctive features are the relatively high concentration of glutamic acid and alanine, and the absence of both hydroxyproline and hydroxylysine, these latter features eliminating the possibility that the enamel cuticular structure under investigation is wholly or partly collagenous in nature. The apparent absence of detectable amounts of sulphur-containing amino-acids implies the absence of keratin structures. Nor do the results lend support to the concept of a haematogenous origin for the pellicle: human haemoglobin contains relatively large amounts of leucine, lysine and histidine, but no isoleucine—features not observed in the pellicle analyses. In the analyses of acquired pellicle only 43 per cent to 45 per cent of the total material was accountable for as amino-acids, and some 4 per cent to 5 per cent was shown to be hexosamine. Carbohydrate analysis using an anthrone method[6] gave total carbohydrate contents of about 15 per cent, a result representing a minimum value for the carbohydrate components. The pellicle amino-acid levels show a fair degree of similarity to those in the salivary mucin hydrolysate, the main difference being the lower levels of

alanine and ornithine in the mucin sample. Like the pellicle, only about half the mucin sample was accounted for as amino-acids, the mucin also containing large amounts of carbohydrate material, including hexosamine. From these results it can be inferred that the acquired pellicle on human tooth enamel is probably a structure derived from salivary material.

In chromatograms of the acquired pellicle there were small amounts of components not identifiable as common amino-acids. One such component, both from its position on the chromatograms and its non-separability from an added synthetic sample of muramic acid, led to its tentative identification as this substance. Since muramic acid is a component specifically associated with bacterial cell walls its presence, if confirmed, would indicate a degree of contamination of the pellicle by bacteria, a feature which is also inferred by routine bacteriological staining of individual pellicles. It is considered that the bacterial cell wall content of the pellicle could be as high as 40 per cent or more.

In summary, the acquired pellicle on human tooth enamel shows compositional similarities to human salivary mucin and it seems probable that the structure is a material of salivary origin with significant quantities of bacteria embedded or attached to it. The purchase of the Technicon automatic amino-acid analyser was made possible by a grant from the Medical Research Council.

Structure of 'Complex' Phospholipids

COLLINS has given evidence for the presence of 'complex' phospholipids in animal tissues, and he suggested that they contained a phosphate triester group. He further suggested that they break down on silicic acid to give moieties having the currently accepted structures of the known phospholipids[1,2]. Considerations of stability led de Koning to put forward alternative structures involving pyrophosphate bonds[3].

As both suggested classes of structure have no negatively charged groups, micelles formed from a naturally occurring phospholipid mixture containing a high proportion of 'complex' phospholipids should bear a net positive charge due to the primary amine and quaternary ammonium groups. To test this possibility, measurements of electrophoretic mobility were made on emulsions of hen's egg yolk phospholipid and sheep brain phospholipid, both extracted according to the method of Wheeldon and Collins[4].

The electrophoretic mobilities were measured in the microelectrophoresis apparatus of Bangham *et al.*[5] at 25° C, and the results are presented in Fig. 1. Except for the lecithin, which exists as a zwitterion over a wide range of *p*H (ref. 6), the samples were negatively charged at *p*H values higher than the *p*K of carboxyl and primary phosphate groups. The mobility of the egg yolk phospholipid (curve *B*) is that to be expected from a mixture of 80 per cent of lecithin (curve *A*) and 20 per cent of phosphatidyl ethanolamine (curve *C*), both of which were isolated by silicic acid chromatography. This agrees with the accepted composition[7]. The high negative charge on the sheep brain phospholipid (curves *D* and *E*) is, however, inconsistent with the suggestion that 60 per cent of the phospholipids in sheep brain are in the form of tertiary esters[1].

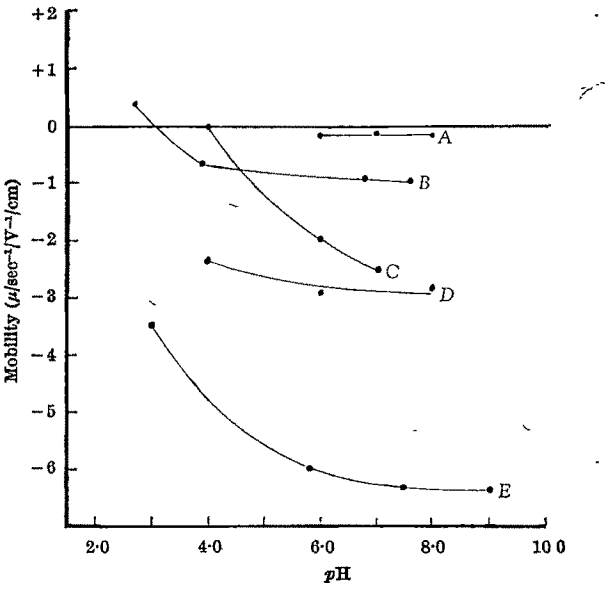

Fig. 1. The electrophoretic mobility of phospholipid micelles at various *p*Hs. The *p*H was adjusted by addition of sodium hydroxide or hydrogen chloride. *A*, Lecithin, isolated from hen egg yolk phospholipids by silicic acid chromatography, emulsified in 0 01 M sodium chloride; *B*, freshly isolated hen egg yolk total phospholipid emulsified in 0 01 M sodium chloride; *C*, phosphatidyl ethanolamine, isolated from hen egg yolk phospholipids by silicic acid chromatography, emulsified in 0·01 M sodium chloride; *D*, freshly isolated sheep brain phospholipid emulsified in 0·1 M sodium chloride; *E*, freshly isolated sheep brain phospholipid emulsified in 0 01 M sodium chloride

In general the net negative charge of naturally occurring phospholipid micelles is well documented[8] and, apart from the rather unlikely possibility that the charge on the surface of a phospholipid micelle does not reflect the ionogenic groups of the molecules forming it, the 'complex' phospholipids cannot have the tertiary ester phosphate structure suggested by Collins[1] or the pyrophosphate structure suggested by de Koning[3].

The experimental work was carried out at the Institute of Animal Physiology, Babraham, Cambridge, England. I am indebted to Dr. A. D. Bangham for the use of his microelectrophoresis apparatus.

Dehydrogenase Isoenzymes from Legume Root Nodules

ALTHOUGH dehydrogenase isoenzymes, especially lactate dehydrogenases, have been extensively studied in vertebrate tissues[1–4], there is little information available about molecular heterogeneity among plant dehydrogenases. During enzymological studies of root nodules from three different legume species, multiple forms of lactate dehydrogenase (L-lactate NAD oxidoreductase; 1.1.1.27), malate dehydrogenase (L-malate NAD oxidoreductase; 1.1.1.37) and glucose-6-phosphate dehydrogenase (D-glucose-6-phosphate NADP oxidoreductase; 1.1.1.49) were observed when the soluble proteins were separated by starch-gel electrophoresis[5].

The plants—*Glycine max*, *Medicago sativa* and *Trifolium repens*—were grown in quartz sand supplied with a modified Crone's nitrogen-free solution[6] and suitable strains of nodule bacteria. After 7 weeks, the nodules were removed and crushed in a Potter-Elvehjem homogenizer. The homogenate was centrifuged at 30,000*g* for 30 min at 0° C and the clear supernatant was used for electrophoresis.

After electrophoresis[7], dehydrogenases were located on the gels by a method essentially the same as that of Markert and Ursprung[8]. For visualizing different dehydrogenases, individual gels were placed in one of the following solutions and incubated at 18° C for 16 h. The medium for locating lactate dehydrogenase[9] was prepared immediately before use from 9·0 ml. 0·5 M sodium lactate, 2·0 ml. NAD (10 mg/ml.), 5·0 ml. phenazine methosulphate (1·6 mg/ml.), 5·0 ml. nitro blue tetrazolium (1 mg/ml.), 45·0 ml. 0·2 M *tris*-HCl buffer *p*H 8·0. A similar medium was used for detecting malate dehydrogenase except that 0·2 *M* malic acid was substituted for sodium lactate. For revealing glucose-6-phosphate dehydrogenase, the substrate, coenzyme and buffer from the foregoing reaction mixture were replaced by 9·0 ml. of 0·02 M glucose-6-phosphate (disodium salt), 2·0 ml. NADP (10 mg/ml.) and 45·0 ml. 0·2 M *tris*-HCl buffer *p*H 7·4.

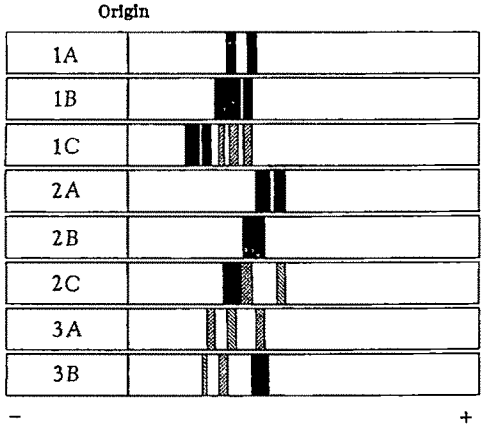

Fig. 1. Dehydrogenase zymograms from legume root nodules. Relative intensities of bands are indicated by shading. 1, *Trifolium repens*; 2, *Medicago sativa*; 3, *Glycine max*; *A*, lactate dehydrogenase; *B*, malate dehydrogenase; *C*, glucose-6-phosphate dehydrogenase

Nodules from different legume species displayed characteristic and reproducible dehydrogenase zymograms (Fig. 1). Two lactate dehydrogenase isoenzymes were visible on zymograms prepared from *T. repens* and *M. sativa*, while those from *G. max* had three isoenzymes. A similar situation was found with malate dehydrogenase, with three isoenzymes on zymograms prepared from *G. max*, two on those from *T. repens* but only one band from *M. sativa*. In contrast, however, when glucose-6-phosphate dehydrogenase zymograms were examined, only one band was detected in *G. max*, while *M. sativa* had three isoenzymes and *T. repens* five.

Further work is in progress, particularly during nodule differentiation, to determine the physiological significance of these multiple dehydrogenases.

I thank Mr. J. Reynolds for technical assistance.

Induction of the Cystine-hypophosphite Reaction by Radical Initiation

THE ability of hypophosphorous acid, or its salts, to reduce the disulphide bond in cystine, peptides and proteins to the corresponding thiols has been reported earlier[1,2]. The reaction is induced either by heating or by irradiation with ultra-violet light.

In the light-induced reaction it has been shown[3] that the thiyl radicals formed by photolysis of the disulphide linkage react with the hypophosphite group (probably as the reactive enol tautomer $(H_3O_2)P\cdot$) to form a quadricovalent phosphoranyl radical of the type proposed by Walling and Rabinowitz[4]. (For the sake of simplicity the formula $(H_3O_2)P$ will be used for hypophosphorous acid as well as its salts and anions.) This radical, (H_3O_2)—$\dot{P}$SCy (where Cy = HOOC—CH(NH_2)—CH_2—), in turn reacts with intact cystine to form a phosphonium-type of double salt $[(H_3O_2)\dot{P}SCy]$-SCy which hydrolyses in water to phosphite and cysteine. Both intermediates are found[3] to be present in the reaction mixture. Neither the radical nor the double salt could be detected in the reaction products of cystine reduced by hypophosphite at elevated temperatures. This is probably due to the instability of these compounds at these temperatures[5].

Initiation of the reaction between cystine and hypophosphite by the use of a radical initiator of the chemical type has now been proved possible and, as in the case of the light-induced reaction, the products contain both the phosphoranyl radical and the double salt. To 5 ml. portions of a solution of cystine (2×10^{-4} M in 0·1 M hydrochloric acid) containing various concentrations of sodium hypophosphite, additions from solutions of hydrogen peroxide (5 μl., 1 vol.) and $FeSO_4(NH_4)_2SO_4 \cdot 6H_2O$ (20 μl., 20 per cent) were made. After about 1 min of gentle shaking, any residual activity of the radical initiator was destroyed by the addition of an equal volume of a saturated solution of the disodium salt of ethylenediamine tetra-acetic acid in water. The thiol content of the solution was then determined by Ellman's method[6]. This experiment was also repeated at *p*H 4·7 (0·2 M acetate buffer) instead of in 0·1 M hydrochloric acid medium.

Table 1. INFLUENCE OF THE HYPOPHOSPHITE CONCENTRATION ON THE EXTENT OF THE REDUCTION OF CYSTINE

Solvent	Hypophosphite concentration (M)	Reduction (per cent)
0·1 M hydrochloric acid	0·01	16·2
	0·10	61·3
	1·00	68·5
0·2 M acetate buffer (*p*H 4·7)	0·01	16 0
	0·10	64·5
	1·00	69·5

The results (see Table 1) show that the extent of the reduction increases with an increase in the hypophosphite concentration. This is in agreement with the observation that the quantum yield of cysteine in the light-induced reaction increases with an increase in the hypophosphite concentration[7]. The reason for this behaviour is that a higher hypophosphite concentration enhances the probability of a thiyl radical reacting with a hypophosphite group before being eliminated by reaction with other compounds.

Paper ionophoresis of the reaction mixture, with 10 per cent acetic acid as electrolyte, showed the presence of two compounds which gave positive reactions with both ninhydrin reagent and the perchloric acid/molybdate reagent[8] (indicating the presence of amino groups and phosphorous compounds, respectively). The ionophoretic mobility of these compounds furthermore corresponded with those of (H_3O_2)—$\dot{P}$SCy and $[(H_3O_2)\dot{P}SCy]$-SCy.

These results show that the cystine/hypophosphite reaction follows a single mechanism regardless of whether the reaction is induced by ultra-violet irradiation or by free-radical initiators. In the latter event the first stage of the reaction—that of the production of a thiyl radical

—is the result of a radical transfer mechanism while the formation of thiyl radical in the former case follows the absorption of light quanta by cystine.

Reversible Action of Pullulanase

THE enzyme pullulanase[1] is a bacterial *R*-enzyme in that it is capable of cleaving certain α 1→6 glucosidic bonds where these occur together with α 1→4 glucosidic bonds as in pullulan, starch and dextrins. The substrate specificity of this enzyme has recently been reported[2] to embrace oligosaccharides and dextrins containing as few as two 1→4 linked α-D-glucopyranoside units in the '*A*' chain and two such units in the '*B*' chain. Thus, a tetrasaccharide linked 2 on 2 is the smallest known substrate for the hydrolytic action of this enzyme[2].

A recently developed technique[3] for examining enzyme action on micro-quantities of individual compounds of a mixture is to separate the compounds in one dimension by chromatography of a single spot on a large sheet of filter paper. The resolved components are then sprayed with an appropriately buffered enzyme, dried, and the ensemble is submitted to chromatography in a direction at right angles to the original direction. Use of this technique revealed that pullulanase acts on branched oligosaccharides (from action of malt α-amylase on amylopectin) to give the expected G_2 (maltose), G_3, and higher linear oligosaccharides. Unexpectedly, a small amount of material with the R_F of a branched tetrasaccharide was also formed from maltose. Thus, there is an apparent synthetic reaction.

We have tested this synthetic action of pullulanase on a larger scale by treating carefully purified, chromatographically pure G_2 with pullulanase, and subjecting the digest to paper chromatography. A well-defined spot appeared in the region characteristic for a tetrasaccharide containing a 1→6 linkage. In addition, there was a weak spot corresponding to a hexasaccharide containing two 1→6 links. No other compounds apart from G_2 appeared. The extent of the reaction was found to be concentration-dependent. in that little tetrasaccharide formed at a G_2 concentration of under 5 per cent, and the amount of tetrasaccharide increased with increasing concentration up to the highest concentration of G_2 we tested (about 25 per cent). Absence of other compounds, specifically D-glucose, indicates that disproportionation or transfer reactions were not involved.

Using G_3 as substrate, we obtained a spot corresponding in position to a hexasaccharide containing a 1→6 link, with no other compounds (except G_3) apparent.

These observations indicate that pullulanase action is reversible through condensation reactions, for example: 2 G_2 → tetrasaccharide + H_2O. With G_2 as substrate, there are two possible 2 on 2 structures; with G_3, there are three possible 3 on 3 structures. Studies in progress should indicate the extent to which each of these structures is produced during the reaction. The interesting possibility arises that pullulanase may condense G_2 and higher oligosaccharides with relatively long amylose chains. Such reactions could occur during the action of pullulanase on amylopectin, thus preventing complete attack by β-amylase. In a test system containing G_2 plus amylose there was definite evidence for condensation.

Similar condensation reactions should be possible with amylase; and, in fact, we were able to obtain a weak G_4 spot from G_2 by action of β-amylase. The amount produced was much less than the amount of tetrasaccharide formed by pullulanase action, however, owing to the difference in free energy of hydrolysis of 1→4 and 1→6 glycosidic bonds.

This work was supported in part by the Corn Industries Research Foundation and the U.S. Public Health Service.

Influence of Cortisone on the Substrate-induction of Enzymes in Rat Liver

Civen and Knox[1,2] and Feigelson and Greengard[3,4] concluded from their experiments with tryptophan-pyrrolase and tyrosine-α-ketoglutarate-transaminase that in animal tissues a distinction can be made between the two types of induction: one caused by substrate and the other caused by hormone. While substrate-induction was found to be due to stabilization of the enzyme and saturation with coenzyme, the cortisone acted by stimulating the synthesis of *m*RNA. The latter process could be inhibited by actinomycin *D*.

Previously we showed that in intact animals actinomycin *D* significantly inhibited substrate-induction of both the enzymes mentioned heretofore[5]. Substrate-induction, therefore, might also be connected with synthesis of *m*-RNA.

We used adrenalectomized rats for our investigations. Tryptophan-pyrrolase and tyrosine-α-ketoglutarate-transaminase were induced either by substrate or small amounts of cortisone or by the combination of both. The activity of tryptophan-pyrrolase was measured by the method of Knox *et al.*[6], the one of tyrosine-α-ketoglutarate-transaminase according to Rosen *et al.*[7].

On injection of 500 mg/kg L-tryptophan the enzyme activity increased 6-fold (see Table 1). This was due, of course, to the stabilization of the enzyme and to the saturation with coenzyme. Actinomycin *D* cannot change this effect. 2·5 mg/kg cortisone instead of L-tryptophan did not bring about any increase of activity. However, in the case of substrate applied together with cortisone, the hormone in an amount which cannot induce tryptophan-pyrrolase by itself, the enzyme activity even rose ten times as much. The additional stimulation is completely prevented by actinomycin *D*.

Neither the injection of 600 mg/kg L-tyrosine nor of 2·5 mg/kg cortisone led to an increase of the enzyme activity (see Table 2). But in combining the two substances one observed a 3-fold higher activity than in the control. Again, this effect does not take place in the presence of actinomycin *D*.

Table 1. INDUCTION OF TRYPTOPHAN-PYRROLASE IN ADRENALECTOMIZED RATS

	+ Cortisone	+ L-Tryptophan	+ Cortisone + L-Tryptophan	+ Cortisone + L-Tryptophan + Actinomycin *D*	+ L-Tryptophan + Actinomycin *D*
1·0 ± 0·4*	0·7 ± 0·3	6·4 ± 1·3	10·3 ± 1·3	5·9 ± 2·3	6·2 ± 2·4

* μMoles kynurenin/g liver/h.

The animals were killed 3 h after the intraperitoneal application of the substances. L-Tryptophan, 500 mg/kg: cortisone, 2·5 mg/kg; actinomycin *D*: 450 μg/kg 1 h before the other substances. Each point 6–10 animals.

Table 2. INDUCTION OF TYROSINE-α-KETOGLUTARATE-TRANSAMINASE IN ADRENALECTOMIZED RATS

+ Cortisone	+ L-Tyrosine	+ Cortisone + L-Tyrosine	+ Cortisone + L-Tyrosine + Actinomycin D
0·25 ± 0 04*	0 22 ± 0 05	0·32 ± 0 08	0·74 ± 0 12	0·36 ± 0 07

* μMoles p-hydroxyphenylpyruvic acid/mg protein/h.

The animals were killed 4 h after the intraperitoneal application of the substances. L-Tyrosine, 600 mg/kg, cortisone, 2 5 mg/kg; actinomycin D, 450 μg/kg 1 h before the other substances. Each point represents 6–10 animals

These results offer the conclusion that in animal tissues substrate-induction is dependent on small amounts of cortisone at least for the enzymes reported. As is known for other hormones, the cortisone seems to activate the synthesis of *m*RNA, which then brings forward the substrate-induction. Therefore we feel that no clear distinction can be made between substrate and hormone-induction.

PHYSIOLOGY

Depolarization of Central Terminals of Group Ia Muscle Afferent Fibres during Desynchronized Sleep

THE stage of deep sleep is characterized by a desynchronized electroencephalogram (EEG), periodic bursts of rapid eye movements and a great reduction of the electromyographic (EMG) activity of dorsal cervical muscles. There is also a tonic depression of spontaneous EMG activity in both flexor and extensor muscles, and a further phasic reduction of residual muscular activity occurs synchronously with the periodic bursts of rapid eye movements[1]. Both the heteronymous[2,3] and the homonymous[4] monosynaptic reflexes are tonically depressed throughout the desynchronized phase of sleep. A further phasic depression frequently occurs at the time of the bursts of rapid eye movements[4]. This suggests that an abrupt but transient increase of the barrage of descending inhibitory impulses occurs phasically in relation to the rapid eye movements of deep sleep[4]. Muscular twitches have also been found to predominate during the bursts of rapid eye movements[1]. These occur, paradoxically, just when the spontaneous muscle activity[1] and the spinal reflexes[4] are most profoundly depressed.

The tonic depression of the monosynaptic reflexes during desynchronized sleep is due to hyperpolarization of the α motoneurones produced by descending supraspinal inhibitory volleys because the recurrent discharge of the α motoneurones is depressed throughout desynchronized sleep[5]. The phasic inhibition of the monosynaptic reflexes that occurs during rapid eye movement has no counterpart, however, in an enhanced depression of the recurrent discharge[5]. This finding led to the prediction[4,5] that the phasic depression of spinal reflexes during the period of rapid eye movement of desynchronized sleep is the result of presynaptic inhibition of the group Iα afferent pathway. The present experiments, in which the excitability of the spinal endings of group Iα muscle afferents was tested following Wall's method[6], have proved this prediction to be correct.

The experiments were performed on unrestrained, unanaesthetized cats. Electrodes for recording the EEG, the EMG of the dorsal cervical muscles and the ocular movements were implanted chronically under 'Nembutal' anaesthesia. The ventral roots from *L4–5* to *S2* were then severed in order to obtain complete de-efferentation. The excitability of Iα primary afferent fibres was tested by recording the antidromic responses to single shock applied unipolarly to the ventral horns through a stainless-steel microelectrode (100,000–600,000 Ω), chronically implanted and completely insulated. The tibial and the deep peroneal nerves were prepared and mounted on chronically implanted bipolar electrodes so that the antidromic response to ventral horn stimulation could be recorded in either the extensor (tibial) or flexor (deep peroneal) muscle afferents. The same electrodes could be used for stimulation.
